1. INTRODUCTION

This summary bridging report integrates the information presented in the two Combined Diphtheria, Tetanus and Acellular Pertussis, Hepatitis B enhanced Inactivated Poliomyelitis and *Haemophilus influenzae* type B vaccine (Infanrix™ hexa) periodic safety update reports (PSURs) covering the two year period from 23 October 2009 to 22 October 2011. Further details are provided below.

Report Number	Dates of Report	Time Period
16	23 October 2010 - 22 October 2011	1 year
15	23 October 2009 - 22 October 2010	1 year

This report presents data on all formulations.

2. WORLDWIDE MARKET AUTHORISATION STATUS

Infanrix™ hexa has been approved in 92 countries (see APPENDIX 1 of PSUR 16).

3. UPDATE ON REGULATORY AUTHORITY OR MANUFACTURER ACTIONS TAKEN FOR SAFETY REASONS

During the period under review, no actions have been taken for safety reasons concerning withdrawal, rejection, suspension or failure to obtain a renewal of a Marketing Authorisation; neither have there been any dosage modifications, changes in target population, formulation changes, restriction on distribution, or clinical trial suspension.

4. CHANGES TO REFERENCE SAFETY INFORMATION

The Reference Safety Information (RSI) in effect at the beginning of the reporting period is the Global Prescriber Information (GPI) of Global Datasheet (GDS) version 9 dated 23 November 2007. Refer to APPENDIX 2A of PSUR 15; the RSI is identified by double-underlining within the GPI.

During the period of this report one new version (version 10) of the RSI was issued. Refer to APPENDIX 2B of PSUR 15; the RSI is identified as grey shaded text within the GPI. In CSI version 10 dated 21 October 2010 the following changes were implemented:

- A warning about the risk of syncope (fainting) after any vaccination was added in the Warnings and Precautions Section: *Syncope (fainting) can occur following, or even before, any vaccination as a psychogenic response to the needle injection. It is important that procedures are in place to avoid injury from faints.*

The following changes were implemented as well in RSI version 10 compared to version 9, although not mentioned in PSUR 15:

- The Company revised the text considered as RSI in the GDS taking into account the fact that any text that refers to ‘negative data’ or ‘no data available’ should not be considered as RSI. As a consequence, the following is no longer considered to be RSI:
 - *Dosage and Administration* Section
 - *Interactions* Section (except for the key message related to higher incidence of fever reported with Infanrix™ hexa)
 - *Pregnancy and Lactation* Section
 - The sentence *The safety profile presented below is based on data from more than 16 000 subjects* in the Clinical Trials Section.
 - *Overdosage* Section
- Several changes were made to the *Use and Handling* Section:
 - wording regarding reconstitution of the vaccine was clarified
 - paragraph related to Bioset presentation was deleted
 - instructions related to PRTC pre-filled syringe and information related to the vial and vial presentation were added
 - a statement regarding disposal of unused products or waste material was added

5. PATIENT EXPOSURE

5.1. Market Experience

Information on the actual number of people exposed to Infanrix™ hexa in the different countries is not available to the MAH. Therefore, the total patient exposure is approximated by the number of doses distributed which is the most reliable data available with regard to patient exposure for a vaccine in a post-marketing setting.

It is important to note that the sales database from which data are retrieved is an in-house ‘living’ database and is subject to updates and corrections depending on information provided by GSK local country subsidiaries (e.g. vaccine doses may be returned by subsidiaries to the central warehouse). These constant updates may result in discrepancies between consecutive queries of the database.

During the period covered by this report 24 283 415 doses of Infanrix™ hexa have been distributed. Since launch until the data lock point (DLP) of this report, 72 931 338 doses have been distributed. As vaccination with Infanrix™ hexa can vary between 1 and 4 doses per subject in accordance with local recommendations and compliance with the vaccination schedule, and assuming that one dose distributed corresponds to one dose administered, post-marketing exposure to Infanrix™ hexa during the SBR reporting

period is estimated to be between 6 070 854 and 24 283 415 subjects. The number of subjects exposed since launch until the data lock point of this report is estimated between 18 232 834 and 72 931 338.

6. INDIVIDUAL CASE HISTORIES

A total of 2408 reports meeting ICH E2C PSUR criteria have been received during the period of this report. These reports include all serious and non-serious reports from spontaneous notifications (including published reports), but exclude all non-healthcare professional reports and all non-serious reports received solely from regulatory authorities. In addition, unblinded, serious attributable reports arising from clinical studies, post-marketing surveillance studies, named patient use or solicited reports following use of a GSK product have been included. These cases are presented within the summary tabulation in Appendix 1.

The tabulation shows the MedDRA System Organ Class (SOC), High Level Group Term (HLGT) and Preferred Term (PT), and the number of unique cases for each adverse event.

The total number of cases presented in line listings and summary tabulations in the series of PSURs appended to this summary report is 2388.

It should be noted that the data-set for the summary tabulation differs from the data-sets included in the individual PSURs during the time period given that the summary tabulation in this report contains follow-up information on cases previously included in the PSURs.

7. STUDIES

7.1. Newly-Analysed Studies

Three new corporate studies relevant to the safety of Infanrix™ hexa were completed and analysed during the period of this report.

- **Study #112157 (DTPa-HBV-IPV=Hib-MenC-TT-002 PRI)** A phase II, open-label, randomised, multicentre study to evaluate the safety and immunogenicity of GSK Biologicals' DTPa-HBV-IPV/Hib-MenC-TT vaccine co-administered with GSK Biologicals' 10-valent pneumococcal conjugate vaccine in healthy infants when administered as a three-dose primary vaccination course at 2, 3 and 4 months of age.

The observed incidence of solicited and unsolicited adverse events was in the same range in the 3 groups, i.e. "Hepta" (candidate heptavalent vaccine), "HexaMnC" (Infanrix™ hexa co-administered with conjugate meningococcal vaccine (Menjugate), and "HexaPn" [Infanrix™ hexa co-administered with conjugate pneumococcal vaccine (Synflorix)]; all the vaccines administered in the study were well tolerated. One SAE (thrombocytopenia) reported for a subject in the Hepta

group was considered by the investigator to have a potential causal relationship to vaccination. All serious adverse events reported during the study resolved without sequelae.

- **Study #110142 (10-PN-PD-DIT-027 PRI)** A phase III randomized, single-blind, controlled study to demonstrate the non-inferiority of co-administration of GSK Biological 10-valent pneumococcal conjugate vaccine with Pediacel™ versus coadministration with Infanrix™ hexa, when administered to infants as a three-dose primary vaccination course during the first six months of life and as a booster dose at 11- 13 months of age.

This study was conducted with 3 parallel groups: “10Pn-Hexa” group received 10Pn-PD-DIT and Infanrix™ hexa, “10Pn-PDC” group received 10Pn-PD-DIT and Pediacel and “Prev-PDC” group received Prevenar and Pediacel. The incidences of grade 3 solicited local and general adverse events were low in all study groups. The percentage of doses followed by unsolicited adverse events was in the same range in all groups. Grade 3 unsolicited adverse events with causal relationship to vaccination were rarely reported. No fatal SAEs were reported in this study up to the data lock point. Up to the data lock point, SAEs after primary vaccination were reported in 32 subjects (17 subjects in the 10Pn-Hexa group, 5 subjects in the 10Pn-PDC group and 10 subjects in the Prev-PDC group). One of these SAEs reported for a subject in the 10Pn-Hexa group (apparent life threatening event) was assessed by the investigator to be causally related to vaccination.

- **Study #111654 (10-PN-PD-DIT-048)** A phase III, multi-centre, double-blind, randomised study to assess the non-inferiority of a commercial lot of GlaxoSmithKline (GSK) Biologicals 10-valent pneumococcal conjugate (10Pn-PD-DiT) vaccine compared to a clinical phase III vaccine lot, when given as a three-dose primary immunization course.

This study was conducted with 2 parallel groups: the “Clin” group received the phase 3 clinical lot of 10Pn-PD-DIT with Infanrix™ hexa or Infanrix-IPV/Hib and HRV, the “Com” group received the commercial lot of 10Pn-PD-DIT with Infanrix™ hexa or Infanrix-IPV/Hib and HRV. All subjects were concomitantly administered a dose of Infanrix™ hexa. The following results are supportive of an acceptable safety profile of the clinical phase III:

Unsolicited adverse events:

The percentage of doses followed by at least one unsolicited symptom in the 31-day postvaccination period was 16.2% in the Clin group and 17.0% in the Com group. The most frequently reported unsolicited AE in each group was upper respiratory tract infection (5.0% in the Clin group and 6.0% in the Com group). The percentage of doses followed by at least one unsolicited symptom considered by the investigator to be causally related to vaccination and the percentage of doses with grade 3 unsolicited AEs in the 31-day post-vaccination period was at most 1.0% in both groups. No grade 3 unsolicited AEs were considered by the investigator to be causally related to vaccination.

Serious adverse events:

No fatal SAEs were reported in this study. A total of 36 non-fatal SAEs were reported for 25 (5.4%) out of 466 vaccinated subjects: 18 subjects (7.7%) in the Clin group and 7 subjects (3.0%) in the Com group. No SAEs were considered by the investigator to be causally related to vaccination. One SAE did not resolve (spinal muscular atrophy) and one SAE (tuberculous meningitis) was still ongoing at the end of this study.

The safety information generated in these studies is consistent with the current safety profile of Infanrix™ hexa.

7.2. Targeted Safety Studies

There were no planned, ongoing or completed targeted safety studies for Infanrix™ hexa.

7.3. Other Safety Studies

The following ongoing studies are not targeted safety studies but were also considered of interest as they may provide useful new information on the safety profile of Infanrix™ hexa:

- **103506 (DTPa-HBV-IPV-118 PRI)** A phase IV, non-randomised, open-label, multi centre study with two parallel groups to assess the immunogenicity and safety of GlaxoSmithKline (GSK) Biologicals combined DTPa-HBV-IPV/Hib vaccine administered as a three-dose primary vaccination course at 2, 4 and 6 months of age in healthy infants in Canada.
- **113948 (DTPa-HBV-IPV-124 PRI)** A phase II, double-blind, randomized, multicentre study to evaluate the safety and immunogenicity of new formulations of GlaxoSmithKline Biologicals DTPa-HBV-IPV/Hib vaccine when administered to healthy toddlers as a booster dose at 12 to 15 months of age.
- **114843 (DTPa-HBV-IPV-125 BST:124)** A phase II, double-blind, randomized, multicentre study to evaluate the safety and immunogenicity of new formulations of GlaxoSmithKline Biologicals DTPa-HBV-IPV/Hib vaccine when administered to healthy toddlers as a booster dose at 12 to 15 months of age.

7.4. Published Safety Studies

A full review of the literature was conducted during the reporting period. Useful information was published during the period concerning:

- safety and reactogenicity of Infanrix-IPV+Hib and Infanrix hexa ([Lim, 2011](#)). Both vaccines were well tolerated and substitution of DTPa-IPV/Hib with Infanrix hexa at Month 5 reduced the number of injections required at this age by one.
- immunogenicity and safety of co-administration of Infanrix hexa with an investigational tetravalent meningococcal serogroups A, C, W-135 and Y-tetanus toxoid conjugate vaccine (ACWW-TT; [Knuf, 2011](#)). Pre-specified criteria for non-

inferiority of immunogenicity following co-administration versus separate ACWY-TT and Infanrix hexa administration were reached, and the safety profile of co-administration was similar to that of Infanrix hexa alone.

These studies did not highlight any safety issue.

8. OTHER INFORMATION

8.1. Late-breaking information

One new fatal case (B0762668A) was received after the data lock point as well as new follow-up data for one of the fatal cases (D0072852A) described in *Section 6.5.1 Cases with a Fatal Outcome* of PSUR 16. Refer to *Section 8.2 Late-breaking information* of PSUR 16 for further information about these cases. The latest CIOMS forms for these cases are attached in APPENDIX 5C of PSUR 16.

8.2. Cumulative review of Gaze palsy

In the assessment report (dated 3 March 2010) of PSUR 14, EMA had the following request:

b. During the period of this report 14 cases of gaze palsy have been identified. In ten of the cases, the event was reported in association with concurrent events, mostly convulsions. However, the median TTO is less than one day. In addition, outcome was reported resolved with sequelae in 1 case and unresolved in 1 case. The MAH is requested to provide a detailed cumulative reviewing of cases of Gaze palsy since launch. The events, TTO, outcome and concomitant drugs should be specified

Accordingly, a cumulative review of cases of Gaze palsy diagnosed after Infanrix hexa administration was performed. All spontaneous reports in the GSK worldwide safety database reported from Infanrix hexa launch up to a data lock point of 22 October 2011 were included in the analysis.

Since launch, 70 spontaneous cases of Gaze palsy were received, corresponding to a reporting frequency of 0.10 per 100 000 Infanrix hexa doses distributed. All cases are summarized in Appendix 2, including time to onset, events, outcome and concomitant drugs reported.

In 45/70 cases the event occurred on the same day of vaccination. In all cases Gaze palsy was one of the presenting symptoms of a larger clinical syndrome, i.e. Febrile and non-febrile Convulsion and Hypotonic-hyporesponsive episode (HHE), which are both listed events in the Infanrix hexa reference safety information.

In 43 cases outcome was reported to be 'Resolved' or 'Resolved with sequelae'. In the other cases outcome was either 'Improved' (N=1), 'Unresolved' (N=6) or 'Unknown' (N=20).

The information received with these cases does not provide evidence of a specific safety concern for Gaze Palsy.

9. OVERALL SAFETY EVALUATION AND CONCLUSION

From the review of data received during the reporting period and presented in this report, it has been concluded that the safety profile of Infanrix hexa is adequately reflected in the RSI.

No further amendments to the RSI are considered necessary at this time.

The benefit/risk profile of Infanrix hexa continues to be favourable.

The Company will continue to monitor cases of anaemia haemolytic autoimmune, thrombocytopenia, thrombocytopenic purpura, autoimmune thrombocytopenia, idiopathic thrombocytopenic purpura, haemolytic anemia, cyanosis, injection site nodule, abscess and injection site abscess, Kawasaki's disease, important neurological events (including encephalitis and encephalopathy), Henoch-Schonlein purpura, petechiae, purpura, haematochezia, allergic reactions (including anaphylactic and anaphylactoid reactions), cases of lack of effectiveness as well as fatal cases.

**APPENDIX 1 : SUMMARY TABULATION OF
INFANRIX HEXA ADVERSE EVENTS**

SUMMARY TABULATION OF INFANRIX™ HEXA ADVERSE EVENTS

23 OCTOBER 2009 TO 22 OCTOBER 2011

N.B. Events are only considered serious if they fulfil GSK medically serious criteria. GSK medically serious criteria are applied automatically only to events from spontaneous, post-marketing or literature case reports. Events arising from Clinical trial cases are not run against the list of GSK medically serious terms. For this reason events may appear as both serious and non-serious (for further details see section 6.1). It should be noted that the end column of the tabulation presents total of cases with event rather than count of events.

APPENDIX 2 : SUMMARY of CASES OF GAZE PALSY SINCE LAUNCH

Summary of cases of Gaze palsy since launch

Case ID	Initial Date Received By Dept	Case Outcome	Age	Gender	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Events PT Comma Sep	Country Of Reporter	Medical Conditions PT Comma
B0559034A	12-Feb-09	Improved	12 Weeks	Male	Infanrix hexa		7 Hours	Febrile convulsion, Gaze palsy, Musculoskeletal stiffness	Poland	
B0564167A	06-Mar-09	Resolved	2 Months	Female	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		3 Minutes	Loss of consciousness, Crying, Pyrexia, Inflammation, Pain, Diarrhoea, Pallor, Gaze palsy, Hypotonia	Netherlands	
B0566112A	20-Mar-09	Resolved	2 Months	Female	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		3 Minutes	Convulsion, Loss of consciousness, Gaze palsy, Depressed level of consciousness, Respiration abnormal, Injection site swelling, Pyrexia, Crying, Decreased appetite, Oligodipsia	Netherlands	Apnoea
B0580036A	19-Jun-09	Resolved	2 Months	Male	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		0 Days	Convulsion, Loss of consciousness, Depressed level of consciousness, Gaze palsy, Oligodipsia, Hypotonia, Pallor, Pyrexia	Netherlands	
B0581097A	26-Jun-09	Resolved	3 Months	Male	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		0 Days	Depressed level of consciousness, Gaze palsy, Sense of oppression, Pallor, Hypotonia, Vomiting, Pyrexia	Netherlands	Nasopharyngitis

Case ID	Initial Date Received By Dept	Case Outcome	Age	Gender	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Events PT Comma Sep	Country Of Reporter	Medical Conditions PT Comma
B0599801A	26-Oct-09	Resolved	2 Months	Male	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		3 Seconds	Depressed level of consciousness, Crying, Hyperhidrosis, Vasodilatation, Gaze palsy, Pyrexia, Inflammation	Netherlands	
B0613669A	09-Dec-09	Resolved	2 Months	Male	Infanrix-polio-HIB, Infanrix hexa		2 Days	Infantile spasms, Gaze palsy, Muscle spasms, Sleep disorder, Condition aggravated, Motor dysfunction, Hypertonia	France	
B0614538A	08-Dec-09	Resolved	2 Months	Male	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		5 Hours	Respiration abnormal, Gaze palsy, Loss of consciousness, Pallor, Cyanosis, Hypotonia	Netherlands	
B0642185A	19-Mar-10	Unknown	15 Months	Female	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		5 Days	Altered state of consciousness, Gaze palsy, Tonic convulsion, Convulsion, Epilepsy, Gastroenteritis, Febrile convulsion, Hypertonia, Ear infection, Gastritis, Nasopharyngitis, Hypotonia, Body temperature increased, Vomiting, Diarrhoea, Pyrexia	Czech Republic	Psychomotor retardation, Psychomotor skills impaired
B0646907A	09-Apr-10	Resolved	11 Months	Male	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		2 Hours	Convulsion, Pallor, Gaze palsy, Loss of consciousness, Hypotonia, Pyrexia, Pain, Fatigue	Netherlands	
B0647634A	13-Apr-10	Resolved	2 Months	Female	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		0 Days	Gaze palsy, Pyrexia, Mental impairment, Crying	Netherlands	

Case ID	Initial Date Received By Dept	Case Outcome	Age	Gender	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Events PT Comma Sep	Country Of Reporter	Medical Conditions PT Comma
B0651462A	03-May-10	Resolved	2 Months	Female	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		6 Hours	Loss of consciousness, Gaze palsy, Pallor, Cyanosis, Hypotonia, Vomiting	Netherlands	
B0652090A	07-May-10	Resolved	12 Months	Male	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		1 Days	Convulsion, Gaze palsy, Loss of consciousness, Pyrexia, Otitis media, Pallor	Netherlands	Nasopharyngitis
B0656946A	21-May-10	Resolved	1 Months	Male	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		8 Hours	Febrile convulsion, Loss of consciousness, Gaze palsy, Pain, Skin warm, Respiration abnormal, Pyrexia, Crying	Netherlands	
B0660020A	10-Jun-10	Resolved	11 Months	Female	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		2 Hours	Pneumonia, Loss of consciousness, Gaze palsy, Convulsion, Nasopharyngitis, Drooling, Pallor, Pyrexia	Netherlands	
B0662920A	03-Jun-10	Resolved	2 Years	Female	Infanrix hexa		5 Hours	Hypotonic-hyporesponsive episode, Depressed level of consciousness, Gaze palsy, Respiration abnormal, Injection site inflammation, Vomiting, Cold sweat, Injection site pain, Pallor, Pyrexia	Netherlands	
B0668856A	05-Aug-10	Resolved	2 Months	Male	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		4 Hours	Gaze palsy, Crying, Pyrexia, Myoclonus	Netherlands	

Case ID	Initial Date Received By Dept	Case Outcome	Age	Gender	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Events PT Comma Sep	Country Of Reporter	Medical Conditions PT Comma
B0669299A	10-Aug-10	Unknown	6 Months	Male	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		0 Days	Epilepsy, Grand mal convulsion, Loss of consciousness, Gaze palsy, Cyanosis, Pyrexia, Salivary hypersecretion, Somnolence, Hyperaemia, Escherichia urinary tract infection, Electroencephalogram abnormal, Drooling, Tremor, Muscle spasms, Partial seizures, I	Italy	Haemangioma, Mental impairment
B0669438A	11-Aug-10	Resolved	16 Months	Male	Infanrix hexa		1 Days	Febrile convulsion, Gaze palsy, Unresponsive to stimuli, Pyrexia	Poland	
B0675842A	22-Sep-10	Unknown	12 Months	Male	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)	Cetirizine hydrochlorid e, Infanrix hexa, Pneumococ cal vaccines (Non-GSK)	4 Hours	Convulsion, Leukocytosis, Shock, Gaze palsy, Loss of consciousness, Pyrexia	Italy	Urticaria
B0681967A	28-Oct-10	Resolved	2 Months	Female	Infanrix hexa, Meningococ cal polysacchari de vaccine group C (Non-GSK), Pneumococ cal vaccines (Non-GSK)		2 Hours	Gaze palsy, Hypotonia, Pallor	Spain	

Case ID	Initial Date Received By Dept	Case Outcome	Age	Gender	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Events PT Comma Sep	Country Of Reporter	Medical Conditions PT Comma
B0682745A	03-Nov-10	Unresolved	6 Months	Male	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		Hours	Convulsion, Loss of consciousness, Gaze palsy, Pallor, Pyrexia, Crying	Netherlands	
B0683261A	05-Nov-10	Resolved	3 Months	Female	Infanrix hexa, Pneumococcal vaccines (Non-GSK)	Magaldrate, Ranitidine hydrochloride	10 Days	Gaze palsy, Hypotonia	Italy	
B0687865A	07-Dec-10	Resolved	11 Months	Male	Infanrix hexa	Priorix	2 Days	Loss of consciousness, Gaze palsy, Pallor, Hypotonia	Italy	
B0690071A	17-Dec-10	Unknown	3 Months	Male	Infanrix hexa, Synflorix		8 Hours	Hypotonic-hyporesponsive episode, Gaze palsy, Opisthotonus, Pallor, Apathy, Fear, Agitation, Hypotonia, Crying	Czech Republic	Dermatitis atopic
B0712712A	05-Apr-11	Resolved	13 Months	Male	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		Hours	Loss of consciousness, Depressed level of consciousness, Convulsion, Gaze palsy, Respiration abnormal, Pallor, Hypotonia, Drooling, Cyanosis, Pyrexia, Vomiting	Netherlands	
B0717794A	06-May-11	Resolved	2 Months	Female	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		36 Hours	Loss of consciousness, Apnoea, Depressed level of consciousness, Gaze palsy, Pallor, Cyanosis, Hypotonia, Peripheral coldness, Pyrexia	Netherlands	
B0722407A	24-May-11	Resolved	2 Months	Male	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		14 Hours	Gaze palsy, Hypertonia, Pyrexia, Dyskinesia, Somnolence, Feeling hot	Netherlands	

Case ID	Initial Date Received By Dept	Case Outcome	Age	Gender	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Events PT Comma Sep	Country Of Reporter	Medical Conditions PT Comma
B0739945A	11-Aug-11	Unknown	5 Months	Male	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		1 Days	Convulsion, Gaze palsy, Clonus, Pyrexia	Italy	
D0042391A	04-Nov-03	Unresolved	2 Months	Female	Infanrix hexa		Same day	Cytomegalovirus infection, Pyrexia, Pallor, Hypotension, Tachypnoea, General physical health deterioration, Gaze palsy, Tachycardia, Hypotonia, Anuria, Transaminases increased, Disseminated intravascular coagulation, Haemolysis, Haematochezia, Hyperkalaemia	Germany	Tobacco user, Alcohol use
D0042827A	07-Jan-04	Resolved	15 Weeks	Female	Infanrix hexa	Infanrix hexa	4 Hours	Hypotonic-hyporesponsive episode, Crying, Hypotonia, Vomiting, Pallor, Altered state of consciousness, Gaze palsy	Germany	
D0044170A	08-Jul-04	Resolved	3 Months	Female	Infanrix hexa		95 Minutes	Tonic convulsion, Opisthotonus, Pallor, Gaze palsy, Muscle twitching, Salivary hypersecretion, Crying	Germany	
D0047035A	07-Jul-05	Unknown	4 Months	Female	Infanrix hexa	Infanrix hexa	9 Days	Nervous system disorder, Developmental delay, Abnormal behaviour, Social avoidant behaviour, Gaze palsy, Syncope, Pallor, Apathy, Extrapyrimal disorder	Germany	Dermatitis atopic

Case ID	Initial Date Received By Dept	Case Outcome	Age	Gender	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Events PT Comma Sep	Country Of Reporter	Medical Conditions PT Comma
D0049384A	12-Apr-06	Resolved	2 Months	Male	Infanrix hexa		10 Minutes	Hypotonic-hyporesponsive episode, Pallor, Hypotonia, Depressed level of consciousness, Gaze palsy, Immobile, Heart rate increased, Areflexia	Germany	Hyperbilirubinaemia, Strabismus, Jaundice
D0049670A	09-May-06	Unknown	5 Months	Female	Infanrix hexa		12 Hours	Epilepsy, Convulsion, Breath sounds abnormal, Gaze palsy, Staring, Depressed level of consciousness, Muscle twitching, Salivary hypersecretion, Crying, General physical health deterioration, Diarrhoea, Gastroenteritis, Haematochezia, Bronchitis, Nausea, V	Germany	
D0054763A	08-Oct-07	Resolved	3 Months	Female	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		0 Days	Hypotonic-hyporesponsive episode, Febrile convulsion, Pyrexia, Urinary tract infection, Leukocyturia, Haematuria, Hypotonia, Movement disorder, Gaze palsy, Pallor, Vaccination complication	Germany	Familial risk factor
D0056301A	27-Feb-08	Resolved	3 Months	Female	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		10 Hours	Hypotonic-hyporesponsive episode, Hypotonia, Retching, Vomiting, Pallor, Gaze palsy, Depressed level of consciousness, Vaccination complication, Gastroenteritis, Abnormal faeces, Diarrhoea	Germany	

Case ID	Initial Date Received By Dept	Case Outcome	Age	Gender	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Events PT Comma Sep	Country Of Reporter	Medical Conditions PT Comma
D0056982A	21-Apr-08	Unresolved	2 Months	Male	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		0 Days	Partial seizures, Developmental delay, Hypotonia, Plagiocephaly, Gaze palsy, Salivary hypersecretion, Daydreaming, Fatigue, Oxygen saturation decreased, Pyrexia	Germany	Vacuum extractor delivery, Foetal monitoring abnormal, Feeding disorder neonatal, Weight decrease neonatal
D0057056A	23-Apr-08	Unknown	4 Months	Female	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)	Zymafluor D, Paracetamol	4 Days	Cerebral haemorrhage, Convulsion, Partial seizures, Status epilepticus, Rhinitis, Somnolence, Oligodipsia, Gaze palsy, Unresponsive to stimuli, Oxygen saturation decreased, Hypothermia, Apnoea, Pallor, Oedema, Pneumonia, Brain oedema, Pyrexia, Pyelonephri	Germany	Premature baby, Respiratory distress, Sleep apnoea syndrome, Bradycardia, Sepsis, Retinopathy congenital, Familial risk factor
D0058126A	21-Jul-08	Unknown	2 Months	Female	Infanrix hexa, Pneumococ cal vaccines (Non-GSK)		0 Days	Epilepsy, Myoclonic epilepsy, Grand mal convulsion, Status epilepticus, Pyrexia, Screaming, Hyperhidrosis, Apathy, Respiration abnormal, Use of accessory respiratory muscles, Gaze palsy, Sleep disorder, Respiratory rate increased, Musculoskeletal stiffnes	Germany	Microcephaly, Foetal growth restriction, Hyperbilirubinae mia, Urinary tract obstruction

Case ID	Initial Date Received By Dept	Case Outcome	Age	Gender	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Events PT Comma Sep	Country Of Reporter	Medical Conditions PT Comma
D0058650A	08-Sep-08	Unresolved	5 Months	Male	Infanrix hexa, DTPa-HepB-IPV-HIB (Non-GSK)		2 Months	Infantile spasms, Grand mal convulsion, Developmental delay, Gaze palsy, Salivary hypersecretion, Fatigue, Skin discolouration, Unresponsive to stimuli, Febrile infection, Otitis media, Hypotonia, Illusion, Neurodermatitis, Atopy	Germany	Delivery, Jaundice neonatal
D0058976A	09-Oct-08	Unknown	3 Months	Male	Infanrix hexa		0 Days	Depressed level of consciousness, Gaze palsy, Somnolence, Vomiting projectile, Pyrexia, Asthenia, Pallor	Germany	
D0059733A	03-Dec-08	Unknown	4 Months	Unknown	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		15 Days	Vaccination complication, Injury, Fluid intake reduced, Fatigue, Listless, Body temperature increased, Vomiting, General physical health deterioration, Insomnia, Crying, Gaze palsy, Dizziness, Haemoglobin decreased, Haemorrhagic anaemia, Thrombosis, Retin	Germany	Premature delivery
D0060368A	03-Feb-09	Resolved with Sequelae	4 Months	Female	Infanrix hexa, Pneumococcal vaccines (Non-GSK)	Infanrix hexa, Pneumococcal vaccines (Non-GSK), Dimethicone	9 Days	Epilepsy, Crying, Gaze palsy, Asthenia, Dyskinesia, Body temperature increased, Gastroenteritis adenovirus, Gastroenteritis norovirus, Dermatitis diaper, Motor developmental delay	Germany	Flatulence, Delivery
D0060421A	06-Feb-09	Resolved	3 Months	Female	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		1 Days	Gaze palsy, Chills, Pyrexia, Vomiting	Germany	

Case ID	Initial Date Received By Dept	Case Outcome	Age	Gender	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Events PT Comma Sep	Country Of Reporter	Medical Conditions PT Comma
D0060869A	13-Mar-09	Resolved	14 Months	Female	Infanrix hexa, Pneumococcal vaccines (Non-GSK)	Infanrix hexa, Pneumococcal vaccines (Non-GSK)	0 Days	Febrile convulsion, Pyrexia, Opisthotonus, Gaze palsy, Tremor, Unresponsive to stimuli, Fatigue, Agitation, Crying	Germany	
D0060889A	16-Mar-09	Unresolved	3 Months	Male	Infanrix hexa, Pneumococcal vaccines (Non-GSK)	Rotavirus vaccine, Paracetamol, Ergocalciferol, Ferrous glycine sulphate	14 Days	Seizure like phenomena, Gaze palsy, Crying, Opisthotonus, Benign familial neonatal convulsions, Epilepsy, Hypertonia, Unresponsive to stimuli, Dyskinesia, Lividity, Psychomotor hyperactivity, Excessive masturbation	Germany	Impetigo, Iron deficiency anaemia, Coordination abnormal, Physiotherapy
D0061561A	07-May-09	Resolved	3 Months	Male	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		1 Days	Convulsion, Cyanosis, Apnoea, Musculoskeletal stiffness, Gaze palsy	Germany	
D0061751A	19-May-09	Resolved	9 Weeks	Male	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		36 Hours	Convulsion, Gaze palsy, Staring, Unresponsive to stimuli, Opisthotonus, Hypotonia, Abnormal faeces	Germany	Plagiocephaly
D0061756A	27-May-09	Unknown	2 Years	Male	Infanrix hexa		1 Days	Febrile convulsion, Pyrexia, Convulsion, Loss of consciousness, Depressed level of consciousness, Musculoskeletal stiffness, Gaze palsy, Cyanosis, Disorientation, Viral infection, Injection site erythema, Injection site swelling	Germany	Fall, Haematoma

16th PERIODIC SAFETY UPDATE REPORT

FOR

Infanrix™ hexa

Date	15 December 2011
Department	Biological Clinical Safety and Pharmacovigilance, GlaxoSmithKline Research and Development Site de Wavre Nord, Avenue Fleming 20, B- 1300 Wavre, Belgium
Drug Name/ Generic	Infanrix™ hexa (Combined diphtheria, tetanus, acellular pertussis, hepatitis B, inactivated poliomyelitis and <i>Haemophilus influenzae</i> type b vaccine)
Review Period	23 October 2010 to 22 October 2011
International Birth Date	23 October 2000 (EU)
Author Daniel De Palmenaer, Safety Scientist  Signature  Date	
Reviewer Dr. Felix Arellano, MD Vice President, Head Biological Clinical Safety and Pharmacovigilance, GlaxoSmithKline Biologicals  Signature  Date	

GSK Biologicals' PSUR template v 2.1

EXECUTIVE SUMMARY

- This is the 16th Periodic Safety Update Report (PSUR) of GSK Biologicals' combined diphtheria, tetanus, acellular pertussis, hepatitis B, inactivated poliomyelitis and *Haemophilus influenzae* type b vaccine (Infanrix™ hexa, hereafter referred to as 'Infanrix hexa') which covers the reporting period between 23 October 2010 to 22 October 2011.
- Infanrix hexa is currently registered in 92 countries. During the period under review, no regulatory actions have been taken for safety reasons.
- There have been no amendments to the Reference Safety Information (RSI) in the current reporting period.
- Post-marketing exposure to Infanrix hexa during the period is estimated to be between 3 075 423 and 12 301 693 subjects. The number of subjects exposed since launch until the Data Lock Point (DLP) of this report is estimated as being between 18 232 834 and 72 931 338.
- The data received during the reporting period referred to a total of 1742 reports of which 1172 cases fulfilled the ICH E2C criteria for inclusion in the main line listings and summary tabulations of this report.
- No further amendment to the RSI is considered necessary at this time.
- No new safety signals were identified and/or evaluated during the reporting period.
- The benefit/risk profile of Infanrix hexa for active immunization of infants against diphtheria, tetanus, pertussis, hepatitis B, poliomyelitis and *Haemophilus influenzae* type b continues to be favourable.
- The Company will continue to monitor cases of anaemia haemolytic autoimmune, thrombocytopenia, thrombocytopenic purpura, autoimmune thrombocytopenia, idiopathic thrombocytopenic purpura, haemolytic anemia, cyanosis, injection site nodule, abscess and injection site abscess, Kawasaki's disease, important neurological events (including encephalitis and encephalopathy), Henoch-Schonlein purpura, petechiae, purpura, haematochezia, allergic reactions (including anaphylactic and anaphylactoid reactions), cases of lack of effectiveness as well as fatal cases.

 APPENDICES	
APPENDIX 1 : Marketing Authorisation Status	233
APPENDIX 2 : Global Data Sheet version 010 - 21 Oct 2010	237
APPENDIX 3A : All serious spontaneous cases (excluding consumer reports), all serious attributable clinical trial cases and all non-serious unlisted cases (excluding consumer and regulatory reports)	253
APPENDIX 3B : All serious attributable clinical trial cases which were received prior to the period of this PSUR but unblinded during the reporting period (no such case was received during the period)	475
APPENDIX 3C : All non-serious listed cases (excluding consumer and regulatory authority reports)	476
APPENDIX 3D : All non-medically verified cases	490
APPENDIX 3E : Cases from a previous period not included in previous PSUR	502
APPENDIX 4A : All reported AEs for cases included in APPENDIX 3A	504
APPENDIX 4B : All reported AEs for cases included in APPENDIX 3C	538
APPENDIX 4C : All reported AEs from non-medically verified serious cases and non-serious unlisted cases (no such case was received during the period)	540
APPENDIX 4D : All reported AEs from non-medically verified non-serious listed cases	541
APPENDIX 4E : Cumulative tabulation of all unlisted events from serious unlisted spontaneous reports and all serious unlisted reactions from clinical trial cases reported since launch	543
APPENDIX 5A : Fatal cases occurred in period	598
APPENDIX 5B : Fatal follow-up cases	629
APPENDIX 5C : Fatal cases - late breaking info	637

1. INTRODUCTION

This is the 16th Periodic Safety Update Report (PSUR) of GSK Biologicals' combined diphtheria, tetanus, acellular pertussis, hepatitis B, inactivated poliomyelitis and *Haemophilus influenzae* type b vaccine (Infanrix™ hexa, hereafter referred to as 'Infanrix hexa') which covers the reporting period 23 October 2010 to 22 October 2011.

This PSUR covers all formulations and indications for the *combination* product Infanrix hexa and is prepared according to all applicable regulations [ICH, 1996; ICH, 2003; Volume 9A, 2008; CHMP/PhVWP, 2007; EMEA/CHMP, 2006].

1.1. Pharmacology and Indications

Infanrix hexa contains the following antigens adsorbed onto aluminium salts: diphtheria toxoid, tetanus toxoid, three purified pertussis antigens (pertussis toxoid [PT], filamentous haemagglutinin [FHA] and pertactin [PRN; 69 kiloDalton outer membrane protein], the purified major surface antigen (HBsAg) of the hepatitis B virus (HBV) and purified polyribosyl-ribitol-phosphate capsular polysaccharide (PRP) of *Haemophilus influenzae* type b (Hib), covalently bound to tetanus toxoid. It also contains three types of inactivated polio viruses (type 1: Mahoney strain; type 2: MEF-1 strain; type 3: Saukett strain).

Infanrix hexa is indicated for primary and booster immunisation against diphtheria, tetanus, pertussis, hepatitis B, poliomyelitis and *Haemophilus influenzae* type b in infants from the age of 6 weeks and may be given to infants who received a first dose of hepatitis B vaccine at birth.

The primary vaccination schedule (such as 2, 3, 4 months; 3, 4, 5 months; 2, 4, 6 months; 3, 5 and 11 or 12 months; 6, 10, 14 weeks) consists of three doses of 0.5 ml. An interval of at least one month should be respected between doses. If it is intended to administer Infanrix hexa according to the EPI schedule (Expanded Program on Immunisation; 6, 10, 14 weeks of age), then the vaccinee must receive a dose of hepatitis B vaccine at birth.

After a vaccination with 2 doses (e.g. 3, 5 months) of Infanrix hexa a booster dose must be given at least 6 months after the last priming dose, preferably between 11 and 13 months of age. After vaccination with 3 doses (e.g. 2, 3, 4 months; 3, 4, 5 months; 2, 4, 6 months) of Infanrix hexa a booster dose may be given at least 6 months after the last priming dose and preferably before 18 months of age.

1.2. Presentations

A 0.5 ml dose of the vaccine contains not less than 30 IU of adsorbed diphtheria toxoid, not less than 40 IU of adsorbed tetanus toxoid, 25 µg of adsorbed PT, 25 µg of adsorbed FHA, 8 µg of adsorbed pertactin, 10 µg of adsorbed recombinant HBsAg protein, 40 D-antigen units of type 1 (Mahoney), 8 D-antigen units of type 2 (MEF-1) and 32 D-antigen units of type 3 (Saukett) of the polio virus. It also contains 10 µg of adsorbed purified capsular polysaccharide of Hib (PRP) covalently bound to 20-40 µg tetanus toxoid (T).

2. WORLDWIDE MARKET AUTHORISATION STATUS

Infanrix hexa was first approved in the European Union on 23 October 2000 (centralized procedure) and is currently licensed in 92 countries. Details of all countries where Infanrix hexa is currently approved are presented in APPENDIX 1. During the period, there was no marketing authorisation withdrawal.

3. UPDATE OF REGULATORY AUTHORITY OR MARKETING AUTHORISATION HOLDER ACTIONS TAKEN FOR SAFETY REASONS

During the period under review, no actions have been taken for safety reasons concerning withdrawal, revocation, rejection, suspension or failure to obtain a renewal of a Marketing Authorisation; neither have there been any dosage modifications, changes in target population, formulation changes, restriction on distribution, or clinical trial suspension.

4. CHANGES TO REFERENCE SAFETY INFORMATION

Changes to the Reference Safety Information (RSI), including rationale, are communicated to Regulatory Agencies on an ongoing basis.

The RSI in effect at the beginning of the reporting period is presented in APPENDIX 2.

The RSI is the Global Prescriber Information (GPI) of the Global Datasheet (GDS) version 10 dated 21 October 2010; the RSI is highlighted in this document by gray shading.

There were no changes to the RSI during the time period of this report.

5. PATIENT EXPOSURE

5.1. Market Experience

Information on the actual number of people exposed to Infanrix hexa in the different countries is not available to the MAH. Therefore, the total subject exposure is approximated by the number of doses distributed which is the most reliable data available with regard to exposure for a vaccine in a post-marketing setting.

It is important to note that the sales database from which data are retrieved is an in-house 'living' database and is subject to updates and corrections depending on information provided by GSK local country subsidiaries (e.g. vaccine doses may be returned by subsidiaries to the central warehouse). These constant updates may result in discrepancies between consecutive queries of the database.

For this PSUR, the database was queried at time of PSUR preparation.

During the period covered by this report 12 301 693 doses of Infanrix hexa have been distributed. Since launch until the data lock point (DLP) of this PSUR, 72 931 338 doses

have been distributed. As vaccination with Infanrix hexa can vary between 1 and 4 doses per subject in accordance with local recommendations and compliance with the vaccination schedule, post-marketing exposure to Infanrix hexa during the PSUR reporting period is estimated to be between 3 075 423 and 12 301 693 subjects. The number of subjects exposed since launch until the data lock point of this report is estimated to be between 18 232 834 and 72 931 338.

Refer to Section 9.4 for pregnancy exposure figures.

6. INDIVIDUAL CASE HISTORIES

6.1. Definitions

LISTEDNESS

Listedness is automatically assigned by GSK at the Medical Dictionary for Regulatory Activities (MedDRA) Preferred Term (PT) level.

Listed Event: An event is only considered listed if it is included in the RSI under all circumstances. Events that are only listed in specific situations (e.g. in overdose, for a specific indication, as part of a hypersensitivity reaction or post-treatment) are assessed as 'unlisted'. Lack of efficacy is assessed as listed. This is supported by CIOMS V which acknowledges that no vaccine can be expected to be effective in all patients.

Listed Case: A case is considered listed if all Adverse Events (AEs) are covered by the RSI when it is entered onto the safety database. This may be different from the RSI used for this PSUR. Note: For clinical trials and Post-Marketing Surveillance (PMS) cases, only serious, attributable events must be in the RSI for the case to appear as listed.

Unlisted Case: A case where at least one AE was not covered by the RSI at the time of case entry.

SERIOUSNESS

Serious Case: A case involving an untoward medical occurrence that results in death, is life-threatening, requires hospitalisation or prolongation of existing hospitalisation, results in disability/incapacity or is a congenital anomaly/birth defect.

Medical or scientific judgement is exercised in deciding whether other reports should also be considered serious, such as those involving important medical events that may not be immediately life-threatening or result in death or hospitalisation but may jeopardise the subject or may require medical or surgical intervention to prevent one of the other outcomes listed in the above definition. These events are also considered serious. Examples of such events are invasive or malignant cancers, intensive treatment in an emergency room or at home for allergic bronchospasm, blood dyscrasias, convulsions that do not result in hospitalisation, or development of drug dependency or drug abuse. In GSK, such medically important events are termed GSK 'medically serious AEs' (see below).

GSK Medically Serious AE: As proposed by CIOMS V, GSK maintains a list of all events considered to be ‘medically serious’ that is regularly reviewed and updated by the company Safety Physicians. This list of MedDRA Lower Level Terms (LLTs) is automatically applied to all spontaneous, post-marketing and literature cases as they are entered onto the safety database. Inclusion of ‘medically serious’ events makes the case serious at case level.

OTHER DEFINITIONS

Attributability: A clinical trial case is classified as ‘attributable’ if the investigator or the company consider there is a reasonable possibility that a serious AE was caused by the study medication. These cases may also contain individual non-serious AEs. A clinical trial case is also considered ‘attributable’ if the investigator does not specify causality for any serious AE.

Primary Adverse Event: The main AE described by the reporter. If a diagnosis and associated signs/symptoms have been provided, GSK will consider the diagnosis the primary AE. Where the main AE is not clear, GSK assigns the most serious medical condition the reporter thought was associated with the drug as the primary AE.

6.2. Cases Presented as Line Listings

The following type of cases received by GSK from worldwide sources during the reporting period and referenced below are considered to fulfil ICH E2C criteria for inclusion in the main line listings and/or summary tabulations of this report:

- all serious adverse reactions and non-serious unlisted adverse reactions from spontaneous notifications (including published reports);
- all non-serious listed adverse reactions from spontaneous reporting;
- all serious adverse reactions (attributable to the vaccine by either investigator or sponsor) available from studies or named-patient/compassionate use;
- all serious adverse reactions from regulatory authorities.

In addition, the type of cases mentioned below is included as a line listing as well:

- all serious and non-serious (listed and unlisted) adverse reactions reported by patients/consumers and other non-healthcare professionals (non-medically verified cases).

The type of cases making up the PSUR line listings within Appendices 3 is summarized below and in [Table 1](#).

APPENDIX 3A contains:

CONFIDENTIAL

CONFIDENTIAL

- all serious cases from spontaneous notifications (including published reports and regulatory reports but excluding non-medically verified reports);
- all unblinded serious cases arising from clinical trials considered related by sponsor or investigator;
- all non-serious unlisted cases from spontaneous notifications (including published reports but excluding non-medically verified reports and reports received solely from regulatory authorities).

APPENDIX 3B contains all serious attributable clinical trial cases unblinded during the reporting period which were not included in a previous report because they were still blinded.

It is company policy that only those clinical trial reports which are expedited to regulatory authorities are unblinded on the safety database during study conduct. Clinical trial reports that are not expedited will be unblinded on study completion. Any clinical trial reports meeting ICH E2C criteria but not included in a previous PSUR, are included as follow-up information in APPENDIX 3B.

In order to ensure no cases are missed, GSK uses a broad search strategy to retrieve clinical trial cases unblinded during the reporting period. Therefore, APPENDIX 3B may include some cases which have already been included in a previous PSUR (e.g. non-blinded clinical trial cases).

Note that no such case was received during the period.

APPENDIX 3C contains all non-serious listed cases from spontaneous notifications including published reports but excluding all non-medically verified reports and all reports received solely from regulatory authorities.

APPENDIX 3D contains all non-medically verified cases, whether serious or non-serious, listed or unlisted.

Table 1 Appended Line Listings

Format	Appendix	Case Type
Line Listing	3A	All serious spontaneous cases (excluding consumer reports), all serious attributable clinical trial cases and all non-serious unlisted cases (excluding consumer and regulatory reports)
	3B	All serious attributable clinical trial cases which were received prior to the period of this PSUR but unblinded during the reporting period <i>No such case was received during the period</i>
	3C	All non-serious listed cases (excluding consumer and regulatory authority reports)
	3D	All non-medically verified cases
	3E	Cases from a previous period not included in previous PSUR

Explanation of line listings content

- Within the line listings a case is considered serious if it fulfils the ICH definition of serious (see Section 6.1). Serious cases are identified by a “#” beside the case ID.
- An unlisted case contains at least one AE that is not covered by the RSI which was in place at the time of data entry.
- The AEs within a case are presented at MedDRA PT level. System Organ Class (SOC) is assigned automatically according to the Primary AE.
- Literature citations for all published cases are noted in the ‘Comments’ column of the line listing.

6.3. Cases Presented as Summary Tabulations

An aggregate summary for each of the line-listings is presented in Appendices 4 as summarised below and in Table 2. All AEs are presented at MedDRA PT level within summary tabulations.

APPENDIX 4A contains all reported AEs for cases included in APPENDIX 3A, meaning AEs from all serious spontaneous cases (excluding consumer reports), all serious attributable clinical trial cases and all non-serious unlisted cases (excluding consumer and regulatory reports).

APPENDIX 4B contains all reported AEs for cases included in APPENDIX 3C, meaning AEs from all non-serious listed cases (excluding consumer and regulatory authority reports).

APPENDIX 4C contains all reported AEs from non-medically verified serious cases + non-medically verified non-serious unlisted cases.

APPENDIX 4D contains all reported AEs from non-medically verified non-serious listed cases.

APPENDIX 4E is a cumulative tabulation of all unlisted events from serious unlisted spontaneous reports (including non-medically verified reports) and all serious unlisted reactions from clinical trial cases reported since launch.

Of note, differences may appear between numbers in the previous PSUR cumulative counts of unlisted events for the following reasons:

- changes in the listedness of some AEs due to an update in the RSI;
- increased consistency in the listedness assessment has been achieved following implementation of an automated listedness attribution applied to the case reports received;
- in “old” cases diagnostics could have been coded with signs and symptoms. These signs and symptoms are not included in the cumulative count anymore.
- in the previous tables all AEs, listed and unlisted were taken into account while in the new outputs, only the unlisted AEs are provided.

Table 2 Appended Summary Tabulations

Summary Tabulation	4A	All reported AEs for cases included in APPENDIX 3A
	4B	All reported AEs for cases included in APPENDIX 3C
	4C	All reported AEs from non-medically verified serious cases and non-serious unlisted cases
	4D	All reported AEs from non-medically verified non-serious listed cases
	4E	Cumulative tabulation of all unlisted events from serious unlisted spontaneous reports and all serious unlisted reactions from clinical trial cases reported since launch

Explanation of summary tabulations content

The following information is important when evaluating the summary tabulations.

Seriousness

AEs from spontaneous, post-marketing or literature cases are only classified as serious within the tabulations if they are on the list of GSK medically serious terms (see Section 6.1). Therefore, although an AE may reside in a case that fulfils the ICH criteria of serious, if the event is not on the list of GSK medically serious terms it will appear within the non-serious column in the summary tabulations.

GSK believes that applying the GSK medically seriousness criteria to AEs will provide a consistent and more meaningful presentation of data within the tabulations, and help with aggregation of terms for signal review activities. Counts of events are presented in the tabulations for the reporting period of the PSUR and cumulatively (APPENDIX 4E).

Note: In rare situations an event may appear in both the serious and non serious columns within the summary tabulations, this may occur for the following reasons:

- *GSK only applies its list of medically serious terms to events reported in spontaneous reports, literature cases and post-marketing surveillance studies. Serious criteria for events originating from clinical trial cases are determined by the reporter. Therefore, as events can originate from different report sources seriousness assessments may differ.*
- *The GSK medically serious list is compiled at the MedDRA LLT level. Summary tabulations present counts of events at the MedDRA PT level. A PT may therefore have both serious and non serious LLTs associated with it.*

6.4. Overview

An overview of the 1742 reports received in the time period is presented in [Table 3](#). Out of this grand total of 1742 cases, 1736 were reported spontaneously and six were clinical trial cases. Based on the exposure data presented in [Section 5.1](#), a reporting rate of 14.16 cases per 100 000 doses distributed can be estimated (against 17.36 cases per 100 000 doses distributed during the previous one-year period). This corresponds to a 18.43% decrease in the overall reporting rate and was mainly driven by a decrease in the reporting rate of non-medically verified ('consumer') cases, which decreased by 81.74%.

Table 3 Reports received in Time Period of PSUR

	NUMBER OF CASES
REPORTS FULFILLING ICH E2C CRITERIA	
Serious Unlisted	503
Serious Listed	56
Non-serious Unlisted	545
TOTAL (Line listing)	1104
Non-Serious Listed	68
TOTAL (ICH E2C criteria)	1172
OTHER REPORTS	
Non-Medically Verified	54
Regulatory, non-serious	516
TOTAL (Other reports)	570
GRAND TOTAL (All reports)	1742

TOTAL	1742 (100,0)

CONFIDENTIAL

CONFIDENTIAL

Based on the initial reporting source (Table 5), 1007 cases were received from regulatory authorities (57,8%), 667 from healthcare professionals (38.3%) and 68 cases from non-healthcare professionals (4%).

Table 5 Distribution of cases by source

Source	Number of Cases (%)
Regulatory Authority	1007 (57,8)
Physician	513 (29,4)
Other Health Professional	85 (4,9)
Pharmacist	69 (4,0)
Consumer	63 (3,6)
Literature	3 (0,2)
Other	1 (0,1)
Representative	1 (0,1)
TOTAL	1742 (100,0)

Table 6 shows the numbers of cases by system organ class (SOC) for all AEs received during the period. Note that in this tabulation, seriousness and listedness are assigned at event level.

Table 6 Number of cases by SOC for all AEs received during the period

Event SOC	Number of Cases (%)
General disorders and administration site conditions	1056 30.9
Nervous system disorders	461 13.5
Skin and subcutaneous tissue disorders	358 10.5
Injury, poisoning and procedural complications	330 9.6
Infections and infestations	181 5.3
Psychiatric disorders	165 4.8
Gastrointestinal disorders	141 4.1
Vascular disorders	129 3.8
Respiratory, thoracic and mediastinal disorders	118 3.5
Investigations	82 2.4
Cardiac disorders	79 2.3
Musculoskeletal and connective tissue disorders	69 2.0
Eye disorders	60 1.8
Metabolism and nutrition disorders	59 1.7
Blood and lymphatic system disorders	46 1.3
Immune system disorders	34 1.0
Surgical and medical procedures	18 0.5
Ear and labyrinth disorders	9 0.3
Hepatobiliary disorders	6 0.2
Congenital, familial and genetic disorders	5 0.1
Renal and urinary disorders	5 0.1
Social circumstances	4 0.1
Endocrine disorders	2 0.1
Reproductive system and breast disorders	2 0.1
Neoplasms benign, malignant and unspecified (including cysts and polyps)	1 0.0
TOTAL	3420 100.0

* This number is greater than the Grand total of cases in Table 3 since each case may include AEs from multiple SOC's

In addition to the grand total of 1742 cases, 10 cases were identified as received prior to the period of the present report, but not included in any previous PSUR (APPENDIX 3E). The reasons are as follows:

- For 9 cases (B0591710A, B0631888A, B0637096A, B0674885A, D0060830A, D0061162A, D0063259A, D0066216A, D0066224A) the suspect vaccine name was changed to Infanrix hexa after the data lock point of the previous PSUR.
- Case B0647987A was initially coded as Postmarketing surveillance (PMS) case. These case types are not included in PSURs when they are non-serious (case B0647987A is non-serious). During the period, the case type was corrected to 'Spontaneous' and thus fulfilled the criteria for inclusion in the PSUR.

These cases are described and discussed among adverse events of interest as appropriate in Sections 6.5 and 9.3.

6.5. Manufacturer's Analysis of Individual Case Histories

As a company policy, all incoming AEs are reviewed on an ongoing basis to detect any new safety signal. Once identified, all available data relating to the AEs under review are routinely evaluated in a cumulative manner for a possible causal association with the suspect product.

The selection of the AEs of interest as described in this section is based on the following criteria: reporting frequency, medical significance, severity of the events, mechanisms of action, issues that are being monitored, or requests by regulatory authorities.

The events of interest are described for all cases (irrespective of source, seriousness and listedness) within the PSUR review period. The events from the non-serious reports received solely from regulatory authorities are not included in the Line Listings and Summary Tabulations as per guideline E2C(R1). Separate Line Listings and Summary Tabulations are provided for consumer reports as per guideline E2C(R1). Therefore some reports may be reviewed and described in this section but will not appear in the line listing and summary tabulations of the PSUR.

The events are presented by MedDRA SOC. Reports with a fatal outcome are discussed separately, regardless of the SOC of the primary AE is classified by MedDRA.

Where relevant, a company comment is provided.

6.5.1. Cases with a Fatal Outcome

Thirteen (13) cases with a fatal outcome were received during the reporting period. Narratives are presented in APPENDIX 5A. Note that non-medically verified reports are included. The narratives are produced directly from the safety database using a standard search strategy. The search strategy retrieves all cases in which the patient died or which are coded with MedDRA PTs indicating that death occurred. Thus the case narratives may include reports where the AE outcome is not specified as fatal in the line listings as well as reports of intra-uterine death or stillbirth.

Cases with a fatal outcome are reviewed on an ongoing basis, as described in Section 9.1.

1. B0683335A (Netherlands): Meningitis viral, Convulsion, Yellow skin, Cyanosis, Dehydration, Diarrhoea, Somnolence, Crying, Vomiting

This case was reported by a regulatory authority (NL-College ter Beoordeling van Geneesmiddelen # NL-LRB-111158) and described the occurrence of meningitis in a 2-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenza type b vaccine (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevenar) for prophylaxis. The subject had no medical history and no concomitant medication. On 13 September 2010, the subject received 1st dose of Infanrix hexa (unknown route, unknown injection site), 1st dose of Prevenar (unknown route, unknown injection site). 3 minutes after vaccination, the subject experienced crying and sleepiness on the same day. On 18 September 2010, 5 days after vaccination, the subject was found in bed with eyes half-opened and a blue mouth. His skin was yellow/pale. He vomited pink, foaming milk. No fever was observed (37 degrees C). The boy was hospitalized, diarrhea aggravated and dehydration was diagnosed. Blood test and spinal tap were performed. The boy had several afebrile convulsions and a MRI showed severe damage of the brain. No further treatment was given. On 25 September 2010, 12 days after vaccination, the subject died from viral meningitis. The regulatory authority considered the events were unlikely to be related with vaccination with Infanrix hexa and Prevenar. Additional information has been requested but could not be obtained from regulatory authority (new regulatory number: NL-LRB-116469). It was unknown whether an autopsy was performed.

Company comment: Case of death due to viral meningitis in a 2-month-old male subject 12 days after 1st combined vaccination with Infanrix hexa and Prevenar. There was severe brain damage on MRI. It is unknown whether an autopsy was performed.

2. B0700040A (Sweden): Meningitis, Sepsis, Shock, Pneumococcal infection, Renal impairment, Hepatic function abnormal, Pyrexia, Diarrhea, Vomiting

This case was reported by a consumer and described the occurrence of meningitis in a 9-month-old female subject who was vaccinated with synflorix (GlaxoSmithKline) and combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) for prophylaxis. A physician or other health care professional has not verified this report. Previous and/or concurrent vaccination included Bacillus Calmette - Guerin vaccine (non-gsk) given on 28 October 2010; diphtheria and tetanus toxoids and acellular pertussis vaccine; GlaxoSmithKline given on 20 May 2010; hepatitis B vaccine recombinant; manufacturer unspecified given on 20 May 2010; synflorix; GlaxoSmithKline; given on 20 May 2010. Concurrent medications included Paracetamol for her growing teeth. On 17 August 2010, the subject received 2nd dose of Synflorix (administration site and route unknown, batch number not provided). On 26 November 2010, 101 days after vaccination with Synflorix, the subject experienced fever, vomiting and diarrhea. This continued the whole day between 11 am to 6 pm. She suddenly got better and she was not vomiting and her fever went down. She got fluid replacement and was able to urinate. On 27

November 2010, at 7 am, the subject was not breathing any longer. At the hospital, they tried to save her during 40 minutes. The subject died on 27 November 2010 from meningitis and sepsis. An autopsy was performed and showed abnormal renal function, hepatic function abnormal and possible pneumococcal infection. The body was in shock.

Company comment: Death of a 9 month-old female subject due to meningitis and sepsis 191 days after combined vaccination with Infanrix Hexa and Synflorix.

3. B0706503A (Thailand): Shock, Respiratory arrest, Cardiac arrest, Pyrexia, Somnolence, Hypotonia, Vomiting, Crying, Apnoea.

This case was reported by a physician and described the occurrence of fatal shock in a 2-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. The subject was born by C-section. Apgar score was 10 at 0 and 5 min. Birth weight was 3.2 kg and experienced a normal growth and development. Medical condition included a possible genetic abnormality due to a family history of death after vaccination (subject's brother died 2 years ago after vaccination with DTwP). On 9 March 2011, the subject received unspecified dose of Infanrix hexa (.5 ml, unknown route of administration). The subject was normal before vaccination. On 10 March 2011, 24 hours after vaccination with Infanrix hexa, the subject experienced shock. She experienced low-grade fever, drowsiness and stopped breathing. The subject was floppy and had no heart rate. Cardiopulmonary resuscitation was performed during 3 hours but the subject did not respond to it. The physician considered the events were probably related to vaccination with Infanrix hexa. The subject died on 10 March 2011 from cardiorespiratory arrest. An autopsy was not performed. Follow-up received on 21 March 2011: The subject's brother was 2 month-old when he died (11 years ago), after received DTwP which was EPI vaccine (no record available). After vaccination (no specific time available), the subject experienced vomiting (single episode) and had colicky crying at home. On 10 March 2011, the subject was taken to the clinic due to fever and crying. After massive crying, the subject experienced apnea and no heart beat was detected after stimulation. Cardiopulmonary resuscitation was performed for 10 minutes and subject responded by crying. One hour later, the subject experienced apnea again and resuscitation was continued for 3 hours without any response. Neither lab results nor autopsy results were available. Shock was the final diagnosis.

Company comment: This case described a SUDI (Sudden Unexpected Death in Infancy) in a 2 month-old female subject 24 hours after vaccination with Infanrix hexa. Autopsy or lab results were not provided. There is a notion of post-vaccine death in a sibling.

4. B0712016A (Italy): Hypotonia, Hyperhidrosis, Pyrexia.

This case was reported by a regulatory authority (IT-Agenzia Italiana del Farmaco # 137473) and described the occurrence of hypotonia in a 11-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine.

(Infanrix hexa, GlaxoSmithKline) and pneumococcal vaccines (non-gsk) (Prevenar 13) for prophylaxis. The subject was born after 41 weeks + 3 days, normal pregnancy and spontaneous delivery. Concurrent medical conditions included severe respiratory distress at birth. He was reanimated and resigned from the prenatal intensive care on 20 May 2010. He was not able to feed spontaneously (dysphagia) so a nasogastric tube was inserted with pump infusion. According to the doctor, the subject had contraindication to the vaccine. He was hospitalised from 22 May 2010 to 25 May 2010 due to respiratory distress. From 14 to 21 July 2010 due to seizures. On 18 August 2010, diagnostic results showed cerebral palsy, gastroesophageal reflux, hypoxic-ischemic encephalopathy of grade 3, microcephaly, psychomotor retardation and spastic quadriplegia (mainly the upper limbs). Concurrent medications included Paracetamol (Tachipirina), Vitamin, Vigabatrin, Topiramate, Antibiotics (Antibiotic), Bronchodilator and Steroid. On 25 March 2011, the subject received 3rd dose of Infanrix hexa (intramuscular, right thigh) and 3rd dose of Prevenar 13 (intramuscular, left thigh). On 26 March 2011, 1 day after vaccination with Infanrix hexa and Prevenar 13, the subject experienced fever (38 to 38.5 deg.C). On 27 March 2011, 2 days after vaccination with Infanrix hexa and Prevenar 13, the subject experienced hypotonia and crisis of sweating. The regulatory authority reported that the events were possibly related to vaccination with Infanrix hexa and Prevenar 13. The subject died on 28 March 2011, cause of death was not reported. It was unknown whether an autopsy was performed. Follow-up information received on 15 July 2011: As no additional information could be obtained, the case has been closed.

Company comment: This case described death of an 11-month old male subject 48 hours after third combined vaccination with Infanrix hexa and Prevenar. The subject died in the context of severe hypoxic-ischemic encephalopathy (cerebral palsy leading to quadriplegia and microcephaly).

5. B0727175A (France): Death.

This case was reported by the French regulatory authority (FR-Agence Française de Sécurité Sanitaire des Produits de Santé # NT20110388) and described the occurrence of unexplained death in a 18-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. The subject had no known and relevant medical history. On 26 October 2010, the subject received an unspecified dose of Infanrix hexa (batch A21CA724A, intramuscular, injection site unknown). On 27 October 2010, 1 day after vaccination with Infanrix hexa, the subject was found dead after her nap. Autopsy did not identify any cause of death. Respiratory aspiration was assessed as not very probable. No other information was available. According to the French method of assessment, the AFSSaPS considered the causal relationship between vaccination with Infanrix hexa and unexplained death as dubious. Autopsy (2010): no identified cause of death.

Company comment: This case described a SIDS in an 18 month-old female subject 1 day after vaccination with Infanrix hexa. No cause was found after autopsy.

6. B0735723A (Australia): Death.

This case was reported by a consumer and described the occurrence of death unspecified in a 6-week-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline), live attenuated human rotavirus vaccine (Rotarix) and pneumococcal vaccines (non-gsk) (Prevenar 13) for prophylaxis. A physician or other health care professional has not verified this report. On 20 July 2011, the subject received unspecified dose of Infanrix hexa (administration site and route unknown), an unspecified dose of Rotarix (route unknown) and an unspecified dose of Prevenar 13 (unknown). On 21 July 2011, 14 hours after vaccination with Infanrix hexa, Prevenar 13 and Rotarix, the subject died for unknown reasons. The subject died on 21 July 2011, cause of death was not reported. An autopsy was performed. Autopsy results are not yet available. Further information has been expected.

Company comment: This case reported a SUDI in a 6-week old male subject 14 hours after combined vaccination with Infanrix hexa, Prevenar and Rotarix. An autopsy was performed but results are not available.

7. D0071496A (Germany): Death

This case was reported by a health professional via a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011016343) and described death of a 3-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and pneumococcal vaccines (non-gsk, Prevenar 13) for prophylaxis. Previous vaccinations with Infanrix hexa and Prevenar 13 (on 14 April 2011) have been well tolerated. On 16 May 2011 the subject received the second dose of Infanrix hexa (intramuscular, unknown thigh) together with the second dose of Prevenar 13 (intramuscular, unknown thigh). At this time the subject had suffered from a mild intestinal infection. In the morning of the following day, on 17 May 2011, the subject was found dead. An autopsy was performed and a preliminary autopsy report was provided. According to the autopsy protocol very early in the morning of 17 May 2011 the subject had been found "cold and lifeless" by her parents. On 05:02 an emergency physician had been called. Cardiopulmonary resuscitation by the parents and later by the emergency personal failed and death was testified. Policemen were involved at 06:20. Interrogation of the subject's parents revealed that the subject and her four siblings had always been healthy. Follow-up information was received from the institut of legal medicine Halle (Saale) on 04 August 2011: The final autopsy report was provided. The causes and mode of death could not be clarified. The infant had been suffering from an acute unilateral otitis media at the time of death (smear from the left middle ear: proof of Haemophilus influenzae; smear from the right middle ear: no proof of microorganisms). Within the scope of additional examinations no alcohol (alcohol concentration 0.00 %) or other pharmacologic could be detected. There was neither evidence of an allergic reaction. (total IgE 5.65 kU/l, reference <20kU/l) nor of a gastrointestinal infection. Nor was there any evidence of a postvaccinal disorder." According to the autopsy report, the onset date of the subject's otitis media was "very recent", but it could not be clarified whether it had been prior to or following the vaccination. Although no evidence of a relation of the event to the vaccination was found during the autopsy, the close

temporal relation might be seen as an indication that the subject's death was possibly related to the vaccination with Infanrix hexa and Prevenar 13.

Company comment: This case described a SUDI in a 13 month-old female subject 1 day after 2nd combined vaccination with Infanrix hexa and Prevenar. A recent acute haemophilus influenzae otitis media was diagnosed on autopsy.

8. D0072663A (Germany): Death

This case was reported by a German regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011029271) and described the occurrence of unexplained death in a 9-week-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenza type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma). Pregnancy and birth had been normal. The subject's medical history included neonatal jaundice. The subject was developing normal. Family history included no allergies. Concurrent medical conditions included suspicion of congenital hip dysplasia. Hip ultrasonography, performed on 09 August 2011, showed type IIa left and type I right. Follow-up hip ultrasonography, performed on 05 September 2011, showed type I both sides. At the time of vaccination, on 05 September 2011, the subject was well. The subject showed small white plaques in oral mucus (oropharyngeal plaques) left but most likely no oral candidiasis. Previous vaccination with Rotavirus vaccine (non-GSK) (RotaTeq; Sanofi Pasteur MSD), given orally at 2 ml on 09 August 2011, was well tolerated. Concurrent medications included colecalciferol + sodium fluoride (D-Fluoretten) and paracetamol (Ben-u-ron). On 05 September 2011 the subject received the first dose of Infanrix hexa (0.5 ml, intramuscular, unknown thigh lateral) and the first dose of Prevenar 13 (.5 ml, intramuscular, unknown thigh lateral). Approximately two days post vaccination with Infanrix hexa and Prevenar 13, on 07 September 2011, the subject died. The cause of death was unknown (death unexplained). The event had also been reported as life threatening. An autopsy was performed on 07 September 2011 at an institute for forensic pathology. At the time of reporting, on 08 September 2011, examinations had not been finished and no autopsy results have been reported. The German regulatory authority (DE-Paul-Ehrlich-Institut) has requested further information. Quality test result was received on 11 October 2011. A complete review of the batch records has been performed by Quality Assurance and Production. No deviation that could impact the quality of the product has been highlighted during the GlaxoSmithKline Biologicals investigation. At the moment no further information was available.

Company comment: This case described a SUDI in a 9 week-old male subject two days after combined vaccination with Infanrix hexa and Prevenar. An autopsy was performed but results are not yet available.

Since 12 September 2011, five cases linked to batch A21CB094A were reported to GSK (D0072663A, D0072852A, D0072638A, D0072908A, D0072920A). All five were serious reports and two had a fatal outcome. A complete review of the batch records was performed by Quality Assurance and Production. No deviation that could impact the quality of the product was highlighted by the GlaxoSmithKline Biologicals investigation. There is insufficient information provided in the individual

case reports to make a thorough causality assessment. Autopsy reports of the fatalities were pending. The three non-fatal cases were all different in nature (no cluster of any kind). These subjects all received Infanrix hexa with either Prevenar 13 or Synflorix. Allergic reactions, febrile convulsions, exanthema and fever are not unexpected to possibly occur after vaccination.

9. D0072852A (Germany): Circulatory collapse, Sepsis, Shock, Crying, Pallor

This case was reported by a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011030856) and described the occurrence of circulatory failure in a 5-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccination included 13-valent pneumococcal vaccine (non-GSK) (Prevenar 13, Pfizer). First vaccination with both vaccines on 23 August 2011 was well tolerated. Information about anamnesis was provided by a hospital report from intensive care treatment after birth. The mother had been pregnant for the first time. The mother had former surgery because of false lung vein opening and received permanent treatment with bisoprolol. The subject was delivered prematurely in 31+4 weeks of gestation, by section from breech presentation after pathologic CTG. There was no premature rupture of the amnion and amniotic fluid was clear. The subject had an APGAR of 6/10/10, a weight of 1490 g, length of 39 cm, head circumference of 32.6 cm, navel artery pH was 7.16. After birth the subject had neonatal respiratory distress syndrome grade I with continuous positive airway pressure for 24 hours. The subject developed possible meconium ileus due to microcolon, transient intestinal transportation disorder, cholestatic hepatosis after parenteral nutrition, with increased transaminases (alanine aminotransferase 131 U/l, aspartate aminotransferase 100 U/l, creatine kinase 342 U/l, total bilirubin 3 mg/dl, direct bilirubin 2.75 mg/dl). Additional diagnoses after birth included neonatal anemia and iron deficiency, asymmetry from lying, small hemangioma right gluteal and dystrophic growth and weight increase. On the sixth day of life, the subject's condition worsened and he was transferred to an intensive care unit for neonates. Intravenous antibiotics were given for seven days. The subject had abdominal distension since birth and not yet passed meconium. Acute abdomen was suspected on the seventh day of life. The subject was transferred to a pediatric surgical unit for further intervention, but after conservative treatment the symptoms resolved. Test results were normal for ions, blood gases, immune reactive trypsin (tested on 06 May and 06 June 2011), sonogram of head, abdomen and hip (Graf classification Ib) and hearing screening. Cytomegalovirus (CMV) and toxoplasmosis IgM and IgG antibodies were negative. Initially increased Thyroid stimulating hormone normalised on control. Bile acid was increased (74.6 mmol/l), pancreatic kinase was decreased (68 mcg/g). Eye examination showed vascularisation limit zone III at both sides. The subject was discharged after 39 days in good condition and received rachitis prophylaxis and iron substitution. On 20 September 2011 the subject received 2nd dose of Infanrix hexa (unknown route and application site), 2nd dose of Prevenar (unknown route and application site). On 20 September 2011 in the evening, less than one day after vaccination with Infanrix hexa and Prevenar, the subject had been crying and turned grey while lying in bed. The vaccinating physician was consulted and admitted the

infant to hospital, where the subject died on 21 September 2011, from circulatory depression or possible sepsis. Different lot numbers were reported on follow-up. Approximately 20 hours after vaccination with Infanrix hexa and Prevenar 13, the subject experienced shock with circulatory failure. An emergency physician was called and the subject was hospitalized on emergency to an intensive care unit. Approximately 10 hours after onset of symptoms the subject died despite intensive care. According to follow-up information received on 07 October 2011 via the German regulatory authority (PEI), the lot number A21CB094A was documented in vaccination certificate, while there was no documentation for the mentioned lot numbers A21CB105A and A21CB115A. Quality test result was received on 11 October 2011. A complete review of the batch records has been performed by Quality Assurance and Production. No deviation that could impact the quality of the product has been highlighted during the GlaxoSmithKline Biologicals investigation. An autopsy was performed. A duplicate case was reported by a physician, via a sales representative and no further details about the reported event were provided.

Company comment: Case D0072949A was identified as a duplicate of case D0072852A that was voided. A complete review of the batch records has been performed and no deviation was evidenced during investigation process. Due to lack of relevant information the causality remains uncertain: possible circulatory or sepsis shock of unknown origin several hours after 2nd vaccination with Infanrix hexa and Prevenar. An autopsy was performed, but the results were not available (see also Section 8.2).

Since 12 September 2011, five cases linked to batch A21CB094A were reported to GSK (D0072663A, D0072852A, D0072638A, D0072908A, D0072920A). All five were serious reports and two had a fatal outcome. A complete review of the batch records was performed by Quality Assurance and Production. No deviation that could impact the quality of the product was highlighted by the GlaxoSmithKline Biologicals investigation. There is insufficient information provided in the individual case reports to make a thorough causality assessment. Autopsy reports of the fatalities were pending. The three non-fatal cases were all different in nature (no cluster of any kind). These subjects all received Infanrix hexa with either Prevenar 13 or Synflorix. Allergic reactions, febrile convulsions, exanthema and fever are not unexpected to possibly occur after vaccination.

10. B0688734A (France): Sudden infant death syndrome, Respiratory tract congestion, Cough, Nasal congestion

This case was reported by the French regulatory authority (AFSSaPS reference PS20101095) and described a sudden infant death in a 10-week-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and pneumococcal vaccine (Prevenar, non-gsk) for prophylaxis. The subject had mixed diet. At birth she weighed 2.99 kg and her height was 49.5 cm. She had no neonatal disorder. Medical condition included jaundice with abnormal skin reflection on 01 October 2010. On 09 November 2010, the subject received primary course of Infanrix hexa (batch A21CA777A as data entry and 121CA777A as reported, intramuscular, injection site unknown) and a

primary course of Prevenar (batch E74711, intramuscular, injection site unknown). On 10 November 2010, the subject presented with bronchial and nasal congestions, cough, and serous fluid in tympanum (with crying at night) which was diagnosed before the administration of vaccines (medical condition). At 19:00, the subject received her last bottle (250 ml). She went to bed at 19:15 and she was layed in her parent's bed, on a pillow. At 21:45, the father went to bed and found the subject unconscious. Mobile emergency medical unit was contacted which arrived at 22:00. At 22:23 pm, a pediatric mobile emergency medical unit arrived. Resuscitation procedure was started. The subject was intubated and received adrenaline. She was hospitalized and died at 00:00. Tracheal aspiration was positive for klebsiella pneumoniae. Causal relationship of vaccination with Infanrix hexa and Prevenar and sudden infant death was assessed as dubious, according to the French method of imputability.

Company comment: Suspected case of SUDI in a 10-week old female subject 1 day after combined vaccination with Infanrix hexa and Prevenar. The subject had an upper respiratory tract infection before vaccination. It is unknown whether an autopsy was performed.

11. B0705290A (France) Sudden death, Pyrexia, Lymphadenopathy, Emphysema, Product quality issue, Cardio-respiratory arrest, Asphyxia, Febrile convulsion

This case was reported by a physician and described the occurrence of death (cause unknown) in a 10-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenza type b vaccine (Infanrix Hexa, GlaxoSmithKline) for prophylaxis. The subject had no known pathology and took no concurrent medication. Vaccinal history included one dose of DTPa-IPV-Hib vaccine (Infanrixquinta, GlaxoSmithKline) administered on and one dose of tuberculosis vaccine (BCG), both administered on 31 August 2010 (information was corrected during AFFSaPS follow-up under reference TO20110471A). The vaccination schedule of the subject did not comply with French medical authority recommendations. The subject's medical history included bronchiolitis during last winter. On 07 March 2011, the subject received a second dose of Infanrix Hexa (batch A21CA598F, route and injection site unknown). During the following night, the subject experienced fever. Mobile emergency medical unit was contacted by the parents. On their arrival, the subject was dead. No diagnostic was made, sudden infant death was suspected. An autopsy was agreed by the parents (not a complete forensic). Results were not available at the time of reporting. According to the reporter, a causal relationship between the death and Infanrix Hexa was not established.

Clinical examination was normal before vaccination. Infanrix Hexa was administered intramuscularly at 11:00 on 07 March 2011. At 15:00, he presented with fever which resolved after paracetamol administration. The evening meal was taken without reportable incident. During the following night, fever recurred and the parents called the mobile emergency unit. On 08 March 2011, the subject was dead on mobile emergency medical unit arrival. He was found, by his father; laid on his stomach with face on his pillow. There were no signs of inhalation or vomiting. There was no sign of righting reflex, normally present at this age. Post mortem

analyses were negative for C-reactive protein, blood culture and cerebrospinal fluid. Post-mortem virus tests were negative excepted positive for Respiratory Syncytial Virus in nose sample. Anatomical pathology evidenced major mesenteric adenopathy. Further information concerning autopsy report were pending. According to the French method of assessment, the AFSSaPS considered the causal relationship between vaccination with Infanrix Hexa and sudden death as dubious. Upon follow-up received from quality department on 31 March 2011: A product complaint has been recorded (Ref 2011-13789). QA analysis revealed the complaint to be unsubstantiated. A complete review of the batch records had been performed and no deviation that could have an impact on the product was highlighted. A search was also performed in the GSK safety database for the final bulk A21CA598 and it did not reveal a safety signal.

A standard follow-up anamnesis was received from a physician on 05 April 2011: no abnormal matters during pre and post-partum conditions. Upon follow-up received from AFSSaPS on 14 April 2011: Autopsy results were provided and evidenced major lymphoid hyperplasia of mesenteric lymph nodes, of intestinal lymphoid tissue and of appendix with cellular dystrophy suggestive of viral etiology possibly subclinical. No Cytomegalovirus, Epstein-Barr virus or Herpes virus infection was found. At lung level, bilateral pseudo-emphysematous pulmonary lesions were noticed, suggestive of suffocation phenomenon as no resuscitation was attempted. No sign suggestive of massive inhalation, no sign suggestive of infectious pneumopathy and no visceral congenital anomaly were reported. According to the AFSSAPS, based on the French method of assessment, the events were unlikely related to vaccination with Infanrix hexa.

Follow-up was received on 21 April 2011 from the AFSSAPS: Psychomotor development was normal. The subject had one half-brother and one half-sister aged 6 and 5 years with medical history of convulsions. The half-brother was treated with Micropakine. On 07 March 2011, at 03:00PM, body temperature was at 39.6 Celsius degrees. On 08 March 2011, around midnight, the father still had not heard from him while he usually woke up at this time for his feed. When the father went to the bedroom, the subject was in ventral decubitus with the face on his pillow; he had cyanosis and was cold. The mobile emergency unit arrived and cardiorespiratory arrest was confirmed (the subject could not be resuscitated). His body temperature was at 35 Celsius degrees. Skull and skeleton ultrasounds were normal.

Company comment: Case of SUDI in a 10-month-old male subject 1 day after a dose of Infanrix hexa (non compliant 2nd vaccination schedule following Infanrix penta + BCG). An autopsy was performed and no clear explanation was found to the subject death. Hypothesis of respiratory asphyxia as cause of death was made, due to circumstances in which the subject was found as well as the aspect of his lungs. Another hypothesis was febrile convulsion. The AFSSAPS reported that the responsibility of respiratory syncytial virus in the inflammatory lesions was unlikely. The time between vaccination with Infanrix hexa and death, was deemed too recent to provide a clear explanation for causality.

- 12. B0716780A (Italy): Cardiac arrest, Multi-organ failure, Pneumonia aspiration, Cerebral, ischemia, Sudden infant death syndrome, Unresponsive to stimuli, Peripheral coldness, Staring, Musculoskeletal stiffness, Pyrexia, Somnolence**

This case was reported by a regulatory authority (IT-Agenzia Italiana del Farmaco # 139520) and described the occurrence of cardiac arrest in a 5-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevenar 13) for prophylaxis. On an unspecified date, the subject received 1st dose of Infanrix hexa (unknown route of administration, unknown site of injection, batch number not provided). At an unspecified time after vaccination with 1st dose of Infanrix Hexa, the subject experienced fever. This is the reason why the second dose was not administered in the last 4 weeks. On 14 April 2011, the subject received 2nd dose of Infanrix hexa (.5 ml, intramuscular, unknown route of administration), and 2nd dose of Prevenar 13 (.5 ml, intramuscular, unknown route of administration, batch number not provided). On 14 April 2011, less than one day after vaccination with 2nd doses of Infanrix hexa and Prevenar 13, the subject experienced fever (more than 39 Deg.C). On 15 April 2011, the fever was resolved. In the afternoon of 15 April 2011, the subject did not respond to stimuli. She was admitted at the first aid with cold extremities, fixed gaze, overtone, stiff neck and normotensive fontanel. Afterwards, the subject recovered completely. At the neurological visit, the subject was alert, reactive and the state of drowsiness has been related to vaccination. Electroencephalogram was without clear anomalies irritative. On 23 April 2011 (night), the subject had a cardiac arrest. After 20 minutes of reanimation the cardiac activity resumed but with irreversible neurological sequelae. The regulatory authority reported that fever, stiff neck, fixed gaze, cold extremities, unresponsive to stimuli and cardiac arrest were possibly related to vaccination with Infanrix hexa and Prevenar 13, but almost certainly for drowsiness. On 25 April 2011, the subject died, cause of death is not specified. It was unknown whether an autopsy was performed. Follow-up information received on 19 May 2011: The parents of the subject were young, both were born in 1992. No information regarding important diseases or neonatal problems were reported. Artificial sucking from the early days due to maternal hypogalactia, was reported. The subject's growth had always been regular, between 50 Deg and 75 Deg percentile. The first dose of the vaccines Infanrix Hexa and Prevenar 13 were administered on 10 February 2011. Within weeks of vaccination with 1st dose of Infanrix Hexa and Prevenar 13, the subject experienced fever. An autopsy was performed and there had been no element attributed to encephalitis. The histological evaluation was in course. Follow-up information received on 6 September 2011: An autopsy was performed and the results were reported on the basis of available information and histological investigations. The death occurred at 15:10 on 25 April 2011. The death was caused by multiple organ failure, ab-ingestis pneumonia, cerebral anoxia, following sudden cardiac arrest. Other significant causes were not found; therefore cardiac arrest might correspond to Sudden Infant Death Syndrome (SIDS). There was no available scientific evidence to show a causal relationship between vaccine administrations and cardiac arrest. Follow-up information received on 14 September 2011: No concomitant medication was reported. The subject was in good health before vaccination. Full report on resuscitation measures and full autopsy report were not available.

Company comment: Case of SIDS in a 5-month-old female subject 1 day after a 2nd dose of combined vaccination with Infanrix hexa and Prevenar. An autopsy was

performed and no clear explanation was found. Therefore cardiac arrest and MOF were placed within a sudden infant death syndrome.

13. D0070324A (Germany): Sudden infant death syndrome, Death, Vomiting, Cardiomyopathy

This case was reported by a physician via another manufacturer and described the occurrence of possible sudden infant death syndrome (SIDS) in a 3-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma). Concurrent or previous medical conditions included hyperbilirubinemia. At the time of vaccination the subject was otherwise healthy. On 18 January 2011 the subject received the first dose of Infanrix hexa (0.5 ml, intramuscular, unknown) and the first dose of Prevenar 13 (0.5 ml, intramuscular, unknown), contralaterally. Less than one week post vaccination with Infanrix hexa and Prevenar 13, In January 2011, the subject experienced possible sudden infant death syndrome (SIDS). The subject died on an unknown date between 18 January 2011 (date of vaccination) and 24 January 2011 (date when police has informed the physician) from possible sudden infant death syndrome (SIDS). It was unknown whether an autopsy was performed. The reporting physician considered that the event was unlikely related to vaccination with Infanrix hexa and/or Prevenar 13. The case was received from Pfizer Pharma GmbH, Berlin, Germany. The other manufacturer has already reported this case under international number DE-PFIZER-INC-2011025551. The same case was reported on 18 February 2011 by the same physician via a sales representative. Approximately three days post vaccination with Infanrix hexa and Prevenar 13, on an unspecified date, the subject was found dead in prone position lying in vomit.

The subject was born by normal delivery at 38 weeks of pregnancy with a birth weight of 3130 g, a length of 49 cm and an Apgar score of 10/10. The subject has no underlying or concurrent medical conditions or other risk factors. On 18 January 2011 the subject received the first doses of Infanrix hexa (lot number: A21CA922C) and Prevenar 13. For the next three days following vaccination with Infanrix hexa and Prevenar 13 the subject was well. Then the subject died from at present unknown cause. The subject was found dead in prone position lying in vomit. An autopsy was performed. At the moment the result of autopsy was unknown. Follow-up information was received on 28 February 2011 from the reporting physician. The reported lot number for Prevenar 13 was E90728, not E40728. According to follow-up information the subject died five days post vaccination with Infanrix hexa and Prevenar 13, on 23 January 2011, and not three days post vaccination with Infanrix hexa and Prevenar 13 as reported initially. The subject has no underlying or concurrent medical conditions or other risk factors. Concurrent medications included colecalciferol + sodium fluoride (D-Fluoretten) for prophylaxis and simethicone (Espumisan) as needed for infantile colic. On 18 January 2011 the subject received the first dose of Infanrix hexa (0.5 ml, intramuscular, left thigh) and the first dose of Prevenar 13 (0.5 ml, intramuscular, right thigh), contralaterally. Approximately five days post vaccination with Infanrix hexa and Prevenar 13, on 23 January 2011, the subject died from at present unknown cause. The subject received no treatment. An

autopsy was performed on an unknown date, but the autopsy report was not available at the moment. According to the reporting physician, in the meantime, there had been signs of possible cardiomyopathy. No further information was available.

Company comment: Case of SUDI in a 3-month-old male subject less than 1 week after 1st dose of combined vaccination with Infanrix hexa and Prevenar. According to the reporting physician, there had been concerns of cardiomyopathy but no further information was available to document this. Autopsy was performed but results not available.

6.5.2. Other adverse event of interest

6.5.2.1. Blood and lymphatic system disorders

6.5.2.1.1. Anaemia haemolytic autoimmune

One (1) case of Anaemia haemolytic autoimmune was reported during the period:

- **D0072751A (Germany): Anaemia haemolytic autoimmune, Autoantibody positive**

This case was reported by a physician and described the occurrence of anemia in a 7-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. On an unknown date in 2011 the subject received the third dose of Infanrix hexa (0.5 ml, unknown). At an unspecified time post vaccination with Infanrix hexa, on an unknown date in 2011, the subject experienced anemia. This case was assessed as medically serious by GSK criteria. Follow-up was received from the physician on 26 September 2011, including a questionnaire. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer). There was no concurrent medical condition or concurrent medication or any other risk factors. On 5 July 2011 the subject received 3rd dose of Infanrix hexa (.5 ml, intramuscular, unknown thigh), together with 3rd dose of Prevenar 13 (intramuscular, the other thigh). On 2 August 2011, 28 days after vaccination with Infanrix hexa and Prevenar 13, the subject experienced autoimmune hemolytic anemia ("Waerme auto antibodies", autoantibody positive). The subject was hospitalised. The subject was treated with blood (Blood transfusion) for several times. At the time of reporting the event was unresolved. The physician considered the event was unlikely to be related to vaccination with Infanrix hexa and and Prevenar 13.

Company comment: A subject developed autoimmune haemolytic anemia within 28 days after vaccination with Infanrix Hexa. The subject was treated with several blood transfusions.

6.5.2.1.2. Autoimmune thrombocytopenia

No case of Autoimmune thrombocytopenia was reported during the period.

6.5.2.1.3. Haemolytic anaemia

No case of Haemolytic anaemia was reported during the period.

6.5.2.1.4. Haemorrhagic diathesis

Two (2) cases of Haemorrhagic diathesis were reported during the period:

- **B0737478A (Poland): Haemorrhagic diathesis, Petechiae, Pyrexia**

This case was reported by a regulatory authority (PL-Office of Medicinal Products # PL-URPL-OCR-20110318006) and described the occurrence of hemorrhagic diathesis in a 4-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-GSK) (Prevenar 13) for prophylaxis. On 18 February 2011, the subject received 2nd dose of Infanrix hexa (intramuscular, unknown injection site), 1st dose of Prevenar 13 (intramuscular, unknown injection site). On 18 February 2011, 8 hours after vaccination with Infanrix hexa and Prevenar 13, the subject experienced fever (38-38.6 deg. C), petechiae and manifestations of hemorrhagic diathesis: small-spot effusions all over the body. The subject was hospitalised. On 18 February 2011, lab test were performed and showed the following: C-reactive protein: 0.32; White blood cell count: 8.5; D dimer: 2184; Activated partial thromboplastin time: 33.1; Fibrinogen: 177; Thrombin time: 17.8; Prothrombin time: 130.06; Smear test from the nose: negative. The second day manifestations yielded. At the time of reporting the events were resolved. No further information can be obtained; this case has therefore been closed.

Company comment: This episode relates to acute febrile petechial signs 8 hours after second dose of Infanrix hexa during combined vaccination with Prevenar. Manifestations yielded spontaneously after 24 hours.

- **D0070397A (Germany): Haemorrhagic diathesis, Ecchymosis, Petechiae, Upper respiratory tract infection**

This case was reported by a physician via a sales representative and described the occurrence of possible hemorrhagic diathesis both lower legs in a 3-month-old male subject who was vaccinated with live attenuated human rotavirus vaccine (Rotarix, GlaxoSmithKline) and combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma). On 08 February 2011 the subject received the first dose of Rotarix (0.5 ml, oral), the first dose of Infanrix hexa (0.5 ml, unknown) and the first dose of Prevenar 13 (0.5 ml, unknown). Approximately one day post vaccination with Rotarix, Infanrix hexa and Prevenar 13, on 09 February 2011, the subject was diagnosed with possible hemorrhagic diathesis both lower legs. On the next day, on 10 February 2011, the subject was hospitalised for an unknown period of time. Laboratory parameters for blood coagulation were normal. Inflammation parameters were normal. The subject experienced no fever. At the time of reporting the outcome of the event was

unspecified. On 08 February 2011 the subject received the first dose of Rotarix (0.5 ml, oral), the first dose of Infanrix hexa (0.5 ml, intramuscular, right thigh, reported lot was not distributed to Germany) and the first dose of Prevenar 13 (0.5 ml, unknown). The following day, on 09 February 2011, the subject was observed with subcutaneous bleedings at both his lower legs. The subject was hospitalised. The physician considered the event was possibly related to vaccination with Rotarix and Infanrix hexa. One day after the vaccination with Rotarix, Infanrix hexa and Prevenar 13, on 10 February 2011, the subject was hospitalized. Overall diagnoses were upper respiratory tract infection, hemorrhagic diathesis, status post vaccination and persistent foramen ovale. According to anamnesis the subject developed subcutaneous bleedings in the morning of the day of hospitalization, on 10 February 2011. There was no fever or restlessness. At the time of hospitalization the subject was noticed with multiple subcutaneous bleedings at both lower thighs and possible petechiae at the knees. The remaining body surface and mucosa was free of bleedings. Gingiva, throat and tonsils were free of bleedings. Mucosa was wet and free of bleedings. Tongue was wet and without coverings. There was no struma. Eyes, ears and nose were normal and free of bleedings. Eardrums were free. Respiration was normal with mixed and equal ventilation and free of aspiratory retractions. The subject's body temperature was 37.4 deg C. The subject was treated with inhalations of sodium chloride solution and Vitamin K. Coagulation tests resulted normally. Hemorrhagic diathesis following vaccination was suspected. The following day, on 11 February 2011, the subject was discharged from the hospital. In another examination within the following days the subject's skin bleedings were found fading and the subject was in a good general condition.

Company comment: This episode relates to acute febrile haemorrhagic signs (bleedings at both lower thighs and possible petechiae at the knees) one day after first dose of Infanrix hexa during combined vaccination with Prevenar and Rotarix in a 3-month-old male subject. There was a context of upper respiratory tract infection and manifestations yielded spontaneously after 24 hours.

6.5.2.1.5. Idiopathic thrombocytopenic purpura

Five (5) cases of Idiopathic thrombocytopenic purpura were reported during the period and are described below. Note that four cases of Thrombocytopenic purpura were also reported during the period (see Section 6.5.2.1.7 Thrombocytopenic purpura).

- **B0684234A (Italy): Idiopathic thrombocytopenic purpura, Thrombocytopenia, Rhinitis, Petechiae, Pyrexia**

This case was reported by a physician via a regulatory authority (IT-Agenzia Italiana del Farmaco # 126680) and described the occurrence of idiopathic thrombocytopenic purpura in a 10-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevenar) for prophylaxis. On 7 April 2010, the subject received unspecified dose of Infanrix hexa (route and injection site unknown) and unspecified dose of Prevenar (route and injection site unknown). On 17 April 2010, 10 days after vaccination with Infanrix hexa and Prevenar, the subject

experienced thrombocytopenia. 48 hours before the admission to the hospital, he presented some petechiae on the face and then all over the body. The subject was hospitalised on 19 April 2010. During the hospitalization, the subject was treated with normal immunoglobulin (Immunoglobulin). On 25 April 2010, 18 days after vaccination with Infanrix hexa and Prevenar, the subject developed fever and serious rhinitis. The diagnosis of idiopathic thrombocytopenic purpura was made. On 7 May 2010, relevant test was performed: bone marrow aspirate showed normal results. On June 201, the subject was treated with corticosteroid due to persistent thrombocytopenia. On 16 July 2010 and on 17 September 2010, platelet counts were respectively $111.000/\text{mm}^3$ and $194.000/\text{mm}^3$. At the time of reporting, the outcome of the events was unspecified. The regulatory authority reported that the thrombocytopenia was possibly related to vaccination with Infanrix hexa and Prevenar.

Company comment: A case of ITP in a 10 month-old subject, 10 days after vaccination with Infanrix Hexa and Prevenar. Autoimmune thrombocytopenia has not been confirmed by positive antiplatelet antibodies. At the time of reporting, the outcome of the events was unknown.

- **B0686840A (Czech Republic): Idiopathic thrombocytopenic purpura, Febrile convulsion, clonic convulsion, Tremor, Dyskinesia, Petechiae, Platelet count decreased, Pyrexia.**

This case was reported by a physician via a regulatory authority (CZ-State Institute for Drug Control # CZ-CZSUKL-10001869) and described the occurrence of idiopathic thrombocytopenic purpura in a 5-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) for prophylaxis. On 7 May 2009, the subject received 2nd dose of Infanrix hexa (intramuscular, injection site unknown, batch number not provided). On 7 May 2009, 3-4 hours after vaccination with Infanrix hexa, the subject experienced fever (38°C). The subject was treated with antipyretics. On 8 May 2010, 1 day after vaccination with Infanrix hexa, the fever raised to 40°C accompanied by shaking of hands and facial jerks during sleep. After awaking by mother, there were no clonic convulsions yet. The subject also developed multiple petechias on skin of lower extremities and trunk. The subject was hospitalised and the regulatory authority reported that the events were clinically significant (or requiring intervention). Relevant tests were performed and showed platelet count which decreased to $7000 \cdot 10^6/\text{l}$. The subject was treated with prednisone (Prednison) and paracetamol (Paralen). The petechias intermittently regressed and erupted during 1 month. The diagnosis was stated as febrile convulsions and idiopathic thrombocytopenic purpura. At the time of reporting, the idiopathic thrombocytopenic purpura, fever and febrile convulsions were resolved. Follow-up information received on 7 January 2011: The subject had a normal growth without serious family and personal anamnesis, but family history of cardiovascular disorder. The subject's mother anamnesis included st. post myocardial infarction. Medical condition included CMV infection which was showed by positive CMV infection test on May 2009. During hospitalization from 13 May 2009 to 15 May 2009, relevant tests were performed: electroencephalogram examination was normal, bone marrow tap did not

proved hemoblastosis. O2 saturation was 91.92%. Platelet count was performed several times: $10 \times 10^9/l$, $10 \times 10^9/l$, $47 \times 10^9/l$ and finally $210 \times 10^9/l$. Blood pH was increased (7.447). Blood count and blood gases were also performed but no results were provided. Follow-up information received on 11 January 2011: The subject was hospitalised on 13 May 2009 for 2 days. The subject's medical condition included CMV infection which was proved by following positive CMV infection test on May 2009: serology showed CMV IgG 3,1; CMV IgM 36; HSV Ig 4,3; EBV VCA IgG 0; EBV VCA IgM 0; EBV EBNA IgG 7, EBV EA IgG 0. Other relevant tests have been performed: Blood test on 13 May 2009 showed thrombocytopenia 10. Other results were in normal range. Biochemistry showed normal results. Neurological examination and psychomotorical development were also normal. At the hospital, the subject was treated with corticosteroids: methylprednisolone sodium succinate (Solumedrol), calcium carbonate (Vitacalcin) and vigantol. On 15 May 2009, the subject was discharged in good condition. On 19 May 2009, a check up showed thrombocytes which increased to 428. Petechias recovered in 1 month, fever, shaking, jerkings or convulsions were not repeated. Then, at the time of reporting the events were resolved. Observation on neurology outpatient clinic was recommended.

Company comment: A case of ITP in a 5 month-old male subject 1 day after vaccination with Infanrix Hexa in the context of concurrent CMV infection. On the basis of the information provided, the time to onset appears short to consider autoimmune thrombocytopenia (no antiplatelet antibodies test performed).

- **B0705987A (Ireland): Idiopathic thrombocytopenic purpura, Haemorrhage, Platelet count decreased, Petechiae, Fall, Increased tendency to bruise, Upper respiratory tract infection**

This case was reported by a pharmacist and described the occurrence of idiopathic thrombocytopenic purpura in a 8-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. In December 2009, the subject completed full course of Infanrix hexa (unknown route, unknown lot number). In January 2010, 1 month after vaccination with Infanrix hexa, the subject experienced idiopathic thrombocytopenic purpura, hemorrhage, platelet count decreased, petechiae, and frequent falls and bruised easily. In 2010, the subject also experienced upper respiratory tract infection treated with rituximab in June 2010. This case was assessed as medically serious by GSK. Relevant test results included: platelet count was 15 then went down to 1. A scan for leukaemia was clear. At the time of reporting, the subject was 22 months old and the outcome of the events was unspecified. The physician was not sure of what caused it. No further information was available at the time of reporting.

Company comment: A case of ITP in a 8-month-old male subject 1 month after vaccination with Infanrix Hexa. A reported recent upper respiratory tract infection may have been a trigger. The outcome of the events is unknown.

- **B0740099A (Netherlands): Idiopathic thrombocytopenic purpura, Petechiae, Diarrhoea, Inflammation, Pyrexia.**

This case was reported by a regulatory authority (NL-College ter Beoordeling van Geneesmiddelen # NL-LRB-119820) and described the occurrence of idiopathic thrombocytopenic purpura in a 4-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-GSK) (Prevenar) for prophylaxis. The subject had no concomitant medication and no medical history. On 6 April 2009, the subject received 2nd dose of Infanrix hexa (unknown route, unknown injection site), 2nd dose of Prevenar (unknown route, unknown injection site). On 6 April 2009, within hours of vaccination with Infanrix hexa and Prevenar, the subject experienced fever (39deg C) for one day. In April 2009, 2 weeks after vaccination, the subject developed petechiae all over the body diagnosed as idiopathic thrombocytopenic purpura. The subject also experienced, at unspecified time after vaccination, diarrhea and inflammation localized. The subject was referred to a pediatrician. This case was assessed as medically serious by GSK. Relevant test results included: in April 2009, thrombocytes: 32. Further investigations showed no abnormalities. After 3 months, thrombocytes elevated to 130. At the time of reporting the events were resolved. The regulatory authority reported that the events were possibly related to vaccination with Infanrix hexa and Prevenar.

Company comment: A case of ITP in a 4-month-old female subject 2 weeks after combined vaccination with Infanrix Hexa and Prevenar. At unspecified time after vaccination, the subject experienced an infectious episode which may have been a trigger. The event resolved spontaneously.

- **D0071950A (Germany): Idiopathic thrombocytopenic purpura, Mouth haemorrhage, Haematoma**

This case was reported by a hospital physician and described the occurrence of idiopathic thrombocytopenic purpura (ITP) in a 12-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. On 30 June 2011 the subject received an unspecified dose of Infanrix hexa (0.5 ml, unknown). Approximately three days post vaccination with Infanrix hexa, on 03 July 2011, the subject was hospitalised for idiopathic thrombocytopenic purpura (ITP). Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma). The subject has no underlying or concurrent medical conditions or other risk factors. The subject received no concomitant medication Previous vaccinations with previous doses of combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma), given on unknown dates, have been well tolerated. On 30 June 2011 the subject received a booster with the fourth dose of Infanrix hexa (0.5 ml, intramuscular, unknown thigh) and a booster with the fourth dose of Prevenar 13 (0.5 ml, intramuscular, unknown thigh). Approximately two days post

vaccination with Infanrix hexa and Prevenar 13, on 02 July 2011, the subject experienced idiopathic thrombocytopenic purpura (ITP). The subject was hospitalised for an unknown period of time. The subject was treated with normal immunoglobulin (Immunoglobulins) and prednisolone (Prednisolon). At the time of reporting, on 14 July 2011, the events were unresolved. The reporting physician considered that the event was probably related to vaccination with Infanrix hexa and Prevenar 13. The reporter provided the answers to a GSK targeted questionnaire for the occurrence of thrombocytopenic purpura: Thrombocytopenic purpura was diagnosed. The symptoms started about two days post vaccination with Infanrix hexa and Prevenar 13. The outcome of the symptoms was unknown. Symptoms included petechiae, ecchymoses / hematoma and hemorrhage specified as hematoma of white trunk of the size of about 1 Euro, oral mucosa ecchymosis and mouth bleeding. Symptoms did not include joint hematoma or joint hemorrhage. Platelet count was 6, 17 and 11 (units not specified) on 03 July 2011, 07 July 2011 and 11 July 2011, respectively (normal range was 150 - 400). Treatment included gamma globulins (Sandoglobulin 4 g; Privigen 4 g) and corticosteroids (Prednisolon 20 mg once daily from 03 July 2011 - 11 July 2011). No relevant medical history has been reported. No further information will be available.

Company comment: A case of ITP in a 12 month-old male subject 2 days after combined vaccination with the 4th dose of Infanrix Hexa (all previous doses were well tolerated) and Prevenar. Treatment included gamma globulins and corticosteroids.

6.5.2.1.6. Thrombocytopenia

Nine (9) cases of Thrombocytopenia were reported during the period:

- **B0684234A (Italy): Idiopathic thrombocytopenic purpura, Thrombocytopenia, Rhinitis, Petechiae, Pyrexia**

See Section 6.5.2.1.5 Idiopathic thrombocytopenic purpura.

- **B0693767A (France): Thrombocytopenic purpura, Petechiae, Haematoma, Epistaxis, Splenomegaly, Thrombocytopenia, Gingival bleeding**

See Section 6.5.2.1.7 Thrombocytopenic purpura.

- **B0694143A (Italy): Thrombocytopenia, Petechiae, Pyrexia**

This case was reported by a regulatory authority (IT-Agenzia Italiana del Farmaco # 132290) and described the occurrence of thrombocytopenia in a 2-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevenar) for prophylaxis. On 4 February 2010, the subject received 1st dose of Infanrix hexa (intramuscular, unknown injection site), 1st dose of Prevenar (intramuscular, unknown injection site). On 5 February 2010, 1 day after vaccination with Infanrix hexa and Prevenar, the subject experienced thrombocytopenia and diffuse petechiae. The subject was hospitalised. Relevant test results included: platelets count: 9000

/mm³. The subject was treated with normal immunoglobulin (Immunoglobulin G) and cortisone. On 12 February 2010, the events were resolved. The regulatory authority reported that the events were possibly related to vaccination with Infanrix hexa and Prevenar. Follow up information received on 01 April 2011: The subject also experienced fever. The subject was hospitalised from 9 to 12 February 2010. Relevant test results included: On 9 February 2010: AST:73 IU/L; Fibrin D-dimer: 2941 ng/ml; On 10 February 2010: Platelet count: 32000 /mm³; Fibrin D-dimer: 2280 ng/ml; On 12 February 2010: Platelet count: 244000 /mm³; Fibrin D-dimer: 1400 ng/ml; AST:63 IU/L; ALT: 41IU/L; LDH: 624IU/L; Urine analysis: negative. The subject was treated with normal immunoglobulin (Immunoglobulin G), cortisone, paracetamol and cefixime. After discharge, the subject was given beclomethasone dipropionate (Clenil) and salbutamol sulphate (Salbutamol) for therapy at home.

Company comment: Thrombocytopenia in a 2-month-old female subject 1 day after vaccination with Infanrix hexa and Prevenar. Pyrexia and elevated inflammatory parameters suggest an infectious cause. Autoimmune thrombocytopenia has not been confirmed (no antiplatelet antibodies test performed).

- **B0695084A (France): Thrombocytopenia, Anaemia, Haematoma, Pyrexia, Gingival bleeding, Fall, Epistaxis, Blood lactate dehydrogenase increased, Incorrect route of drug administration**

This case was reported by the French regulatory authority (AFSSaPS reference PS20110053) and described the occurrence of thrombocytopenia in a 2-year-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and combined measles, mumps and rubella vaccine, live and attenuated (new strain) (Priorix, GlaxoSmithKline) for prophylaxis. The subject had no relevant medical history. On 14 September 2010, the subject received unspecified doses of Infanrix hexa (intramuscular, batch and injection site unknown) and of Priorix (batch and injection site unknown). It was reported that Priorix was administered intramuscularly instead of subcutaneously (wrong route of administration). On the same day, the subject presented with a febrile episode which resolved spontaneously. On 15 September 2010, the subject experienced gingivorrhagia which resolved. On 25 September 2010, a consultation at emergency unit was made due to a fall with secondary frontal hematoma. Neurological examination was normal. The subject was not hospitalized. On the same day, she accidentally fell again. On 26 September, for the third time, she fell headlong. On 27 September 2010, she consulted at emergency unit for epistaxis. Physical examination showed a voluminous frontal and periorbital hematoma. Neurological and ENT examinations were normal. Cerebral CT-scan was normal without fracture. The subject was not hospitalized. On 28 September 2010, epistaxis recurred with worsening of frontal hematoma without new fall. Laboratory tests evidenced hemoglobin at 6.2 g/dl (anemia), reticulocytes at 71000, platelet count at 2000 /l (thrombocytopenia), neutrophils at 11000 /l, prothrombine level at 85 percent, lactate dehydrogenase at 591 (normal<480), ALAT and ASAT normal. The subject received 2 packed red blood cell transfusions and one platelet concentrate resulting in an increased of hemoglobin to 11.4 g/dl, with reticulocytes at 80000.

Platelets remained at 2000 /l. In the evening of 28 September 2010 and on 29 September morning, she received a new platelet concentrate. Hemoglobine was at 10.5 g/dl with platelets at 13160 /l. Blood electrolytes were normal. Fever recurred. Gentamicin sulphate (Gentalline), piperacilline + tazobactam (Tazocilline) and paracetamol (Perfalgan) were started. On 29 September 2010, the subject was transferred in another hospital. Ophthalmological examination (including dilated fundus examination) was normal. Cerebral CT-scan and myelogram (no tumorous cells and good cellularity of bone marrow) were normal. Dexamethasone was started (10 mg/m²). On 01 October 2010, platelets were lower than 10000 /l, hemoglobin was at 9.7 g/dl. Lumbar puncture was sterile. Normal immunoglobulin (Tegeline) was initiated (1g / kg on two days). On 03 October 2010, platelets were at 67000 /l, hemoglobin at 10.3 g/dl. Dexamethasone was discontinued and replaced by prednisone. Antibiotics were discontinued as the subject was afebrile. On 04 October 2010, the subject was discharged from hospital. At the time of reporting, anemia, thrombocytopenia, hematoma and fever were resolved.

Company comment: A case of thrombocytopenia and anaemia in a context of recurring fever of unknown cause starting 1 day after combined vaccination with Infanrix Hexa and Priorix in a 2 year-old female subject. Hematomata due to repetitive falling. The event was resolved with antibiotics, packed red blood cell transfusions, platelet concentrate and steroids.

- **B0699373A (Sweden): Thrombocytopenia, Contusion**

This case was reported by a regulatory authority (SE-Medical Products Agency # 110404) and described the occurrence of thrombocytopenia in a 12-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) and pneumococcal vaccines (non-gsk) (Prevenar) for prophylaxis. The subject's medical history included contusions after previous vaccinations. On 8 November 2010, the subject received an unspecified dose of Infanrix hexa (intramuscular, administration site unknown) and an unspecified dose of Prevenar (intramuscular, unknown). On 16 November 2010, 8 days after vaccination with Infanrix hexa and Prevenar, the subject experienced thrombocytopenia and contusions. 6 months earlier, she had normal platelets. The subject was hospitalised for observation and the platelets rose spontaneously. Lab results: On 15 November 2010: hemoglobin: 118 g/l, platelets: 6 10E9/l, white blood cells: 17.1 10E9/l. On 15 December 2010: hemoglobin: 122 g/l, platelets: 61 10E9/l, white blood cells: 8.4 10E9/l. On 28 December 2010: hemoglobin: 126 g/l, platelets: 159 10E9/l, white blood cells: 11.4 10E9/l. At the time of reporting, the events were resolved. The regulatory authority reported that the events were possibly related to vaccination with Infanrix hexa and Prevenar. As no additional information could be obtained, the case has been closed.

Company comment: A 12-month-old female subject experienced thrombocytopenia and contusions 8 days after vaccination with Infanrix hexa. No clear cause of this event was reported and the symptoms resolved spontaneously.

- **B0724575A (France): Thrombocytopenic purpura, Thrombocytopenia, Petechiae, Injection site haematoma**

See Section 6.5.2.1.7 Thrombocytopenic purpura.

- **D0070216A (Germany): Henoch-Schonlein purpura, Thrombocytopenia, Petechiae, Pyrexia, Upper respiratory tract infection, Anaemia**

See Section 6.5.2.11.3 Henoch-Schonlein purpura.

- **D0071125A (Germany): Thrombocytopenia, Gastroenteritis rotavirus, Leukopenia, Petechiae, Haematoma, Ureteric stenosis, Pyelocaliectasis**

This case was reported by a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011012061), by a Health care Professional, and described the occurrence of thrombocytopenia in a 3-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer). Previous vaccination with Infanrix hexa and Prevenar 13 on 16 February 2011 was well tolerated. On 16 March 2011 the subject received 2nd dose of Infanrix hexa (unknown route and application site), together with 2nd dose of Prevenar 13 (unknown route and application site). On 28 March 2011, 12 days after vaccination with Infanrix hexa and Prevenar 13, the subject experienced thrombocytopenia (Platelet count was 4000 /ul). At the same time, the subject experienced rotavirus gastroenteritis. The subject was hospitalised. Repeated blood examinations were performed. "Initially, the subject additionally experienced mild leukopenia". Hemoglobin was normal, HLA antibodies, thrombocytic allo- or auto-antibodies were negative. Follow-up was received from the regulatory authority (German Regulatory Authority (vaccines, biologicals) on 6 May 2011, including 2 hospital reports and 4 physicians' reports. According to the 1st hospital report, provided on 11 April 2011, the subject was hospitalised due to rotavirus gastroenteritis from 28 March 2011 to 4 April 2011. A distinct thrombocytopenia was diagnosed (Platelet count was 4000 /ul). The subject was treated with platelet concentrate once. Platelet count increased to 39000. One day later platelet count decreased to 12000 again. The subject was treated with normal immunoglobulin (Immunoglobins) and platelet count increased to 60000 on 4 April 2011 and the subject was discharged from the hospital. On an ambulatory control on 7 April 2011, platelet count was 15000. On 8 April 2011 the subject was hospitalised again with a platelet count of 13000. The subject again was treated with normal immunoglobulin (Immunoglobins) with a dosage of 1 g/kg body weight. On 10 April 2011 platelet count increased to 21000. On 11 April 2011 platelet count decreased to 10000 again. Clinically the subject was in good general condition, there was no indication for infection. On 11 April 2011 the subject was transferred to another hospital. During previous hospitalization from 28 March 2011 to 4 April 2011, a stool test for Rotavirus was positive. At that time, the subject experienced petechiae and a small hematoma on the left side. Physical examination on admission on 11 April 2011 was without pathologic findings, especially there were no mucosal bleeding and no hematoma. Thrombopenia was diagnosed. Ureteric stenosis (renal pelvis dilatation) was suspected. There were no

known allergies. Concurrent medications included D-fluorettin. Test for thrombocyt autoantibodies in eluat and for thrombocyt antibodies in plasma on 14 April 2011: In the plasma monospecific thrombocyt autoantibodies were found, which could be indication for existing autoantibodies, despite missing indication from the eluat. In case of previous thrombocyte transfusion these maybe possible thrombocyt alloantibodies. Or they may be cross-reactive antibodies within other underlying diseases like autoimmune disease, infection, CLL, monoclonal gammopathy). Another report, approximately from 18 April 2011, reported there was no splenomegaly, hepatomegaly and no lymph node enlargement. According to a pathological histological expertise from 21 April 2011, a bone marrow punch biopsy was performed. "There were sufficient megacaryocytes of all maturation stages without significant dysplastic maturation disturbances." A bone marrow smear showed "megacaryocytes with the above described morphology." Diagnosis: The bone marrow punch biopsy showed "tangential hit poor subcortical medullary spaces with little granulopoietic hypoplasia, little left-shift of erythropoiesis, interstitial lymphocytosis and hemophagocytosis." The bone marrow smear showed "lymphocytosis, blast cells at limit and abnormal hemophagocytosis. Left-shift of granulopoiesis with poor indication of segmented neutrophils." Clinically thrombopenia and neutropenia were diagnosed. "The morphological changes were not characteristic for myelodysplastic syndrome. The findings point to an immunologic genesis of thrombopenia and neutropenia. Were there indications for a chronic inflammatory underlying disease, maybe Systemic Lupus erythematosus?" Immunohistochemic examinations were planned for exclusion of a blast cell excess. According to a report from 21 April 2011, from the same physician, "immunohistochemic examination showed that CD34-positive precursor cells took approximately 5 to at most 10 %. CD117-positive blast cells were not increased. CD68-positive macrophages were clearly increased, occasional with signs of hemaphagocytosis. There also was increase of CD68-positive monocytes. Only according to these histologic findings it was difficult to decide whether there was a monocytoid propagation of blast cells. The bone marrow smear showed a number of blast cells at limit and a propagation of lymphoid cells (like haematogones). An additional immunohistochemic examination in case of the CD34-positive haematogones was planned. No further information will be available.

Company comment: This 3-month year old female subject experienced thrombocytopenia and neutropenia 12 days after vaccination with Infanrix hexa and Prevenar. There was a concomitant Rotavirus gastroenteritis. The thrombopenia dissolved with immunoglobins. Test for thrombocyt autoantibodies was inconclusive. After reoccurrence of the thrombocytopenia additional investigations were performed (immunohistochemistry and bone marrow smear) to exclude underlying chronic inflammatory disease.

- **D0072425A (Germany): Thrombocytopenia, Petechiae, Haematoma.**

This case was reported by a hospital physician and described the occurrence of thrombocytopenia in 24-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and combined measles, mumps and rubella vaccine, live, attenuated (new strain) (Priorix,

GlaxoSmithKline) for prophylaxis. On an unspecified date the subject received an unspecified dose of Infanrix hexa (0.5 ml, unknown). At an unspecified time post vaccination with Infanrix hexa, on an unspecified date, the subject experienced thrombocytopenia. This case was assessed as medically serious by GSK criteria. At the time of reporting the outcome of the event was unspecified. Follow-up information was received on 14 October 2011 from the reporting hospital physician. In follow-up information the reporting hospital physician reported Infanrix hexa as Infanrix and for the first time vaccination with Priorix. The lot number had not been known. The subject has no risk factors. The subject received no permanent concomitant medication. On 18 July 2011 the subject received an unspecified dose of Priorix (0.5 ml, intramuscular, unknown). On 04 August 2011 the subject received unspecified dose of Infanrix hexa (0.5 ml, intramuscular, unknown). Approximately 24 days post vaccination with Priorix and approximately seven days after vaccination with Infanrix hexa, on 11 August 2011, the subject experienced thrombocytopenia. The subject was hospitalised for an unknown period of time. Platelet count was as low as 1 G/l. Over time platelet count was 17, 67, 101, 148, 140 and 102 G/l. The exact dates of platelet count determination had not been reported. The subject was treated with normal immunoglobulin (Immunoglobulin) and prednisolone (Prednisolon). After about eight days, on 18 August 2011, the event was resolved. The reporting hospital physician considered that the event was possibly related to vaccination with Priorix and Infanrix hexa. Follow-up information was received on 24 October 2011 from the reporting hospital physician. Symptoms of thrombocytopenia included petechiae and hematoma. Platelet count was 1, 17, 67, 101, 148, 140 and 102 G/l on 12 August 2011, 13 August 2011, 14 August 2011, 15 August 2011, 16 August 2011, 18 August 2011 and 20 August 2011, respectively. Follow-up information has been requested.

Company comment: Thrombocytopenia in a 24 month-old subject 7 days post-vaccination with Infanrix Hexa. The event resolved after 8 days of treatment with immunoglobulin and steroids.

6.5.2.1.7. Thrombocytopenic purpura

Four (4) cases of Thrombocytopenic purpura were reported during the period (see Section 6.5.2.1.5 for Idiopathic thrombocytopenic purpura cases):

- **B0693767A (France): Thrombocytopenic purpura, Petechiae, Haematoma, Epistaxis, Splenomegaly, Thrombocytopenia, Gingival bleeding**

This case was reported by the French regulatory authority (AFSSaPS reference PV20100367) and described the occurrence of thrombocytopenic purpura in a 25-week-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, inactivated poliomyelitis and Haemophilus influenzae type b with or without hepatitis B vaccine (unknown manufacturer) and pneumococcal vaccines (Prevenar, non-gsk) for prophylaxis. The subject was born at 39 weeks and 6 days of amenorrhea with a birth weight of 3.5 kg. The subject weighed 6.9 kg and measured 68 cm on admission. Her head circumference was 48 cm. Subject's parents had blood relations. Her mother suffered from migraine. On 21 September 2010, the subject received unspecified doses of unspecified Infanrix (reported batch number G4046,

which was not a GSK batch number) (coded DTPa-HBV-IPV-HIB from unknown manufacturer) and Prevenar (batch E45165). Both vaccines were administered intramuscularly in unknown sites of infection. On 09 October 2010, 18 days after vaccination, the subject presented with palate and tongue petechiae associated with epistaxis which stopped spontaneously. On 10 October 2010, dermatologic examination showed petechiae all over the body and arch of the foot hematoma. Clinical examination showed normal ganglionic area, splenomegaly and no hepatomegaly. Other part of this examination was unremarkable. Laboratory tests evidenced thrombopenia with platelets at 1000 /mcl. Hemoglobine was at 10.3 g/dl, white blood cells were at 9400 /mcl and C-reactive protein at 1 mg/ml. The subject received a first course of normal immunoglobulin (Tegeline) at 1 mg/kg. Platelets rose to 22000 /mcl. As petechiae persisted associated with a mild gingival bleeding which stopped spontaneously, a second course of Tegeline was administered on 12 October 2010. On 14 October 2010, platelets were at 163000 /mcl, hemoglobine at 9.4 g/dl and white blood cells at 8900 /mcl. Physicians concluded to a thrombocytopenic purpura suggestive of an idiopathic thrombocytopenic purpura. On discharge from hospital the subject weighed 6.78 kg. The subject was hospitalised. At the time of reporting, petechiae and hematoma were improved.

Company comment: A case of thrombocytopenic purpura suggestive of ITP in a 25 week-old female subject 18 days after vaccination with combined diphtheria, tetanus-acellular pertussis, inactivated poliomyelitis and Haemophilus influenzae type b with or without hepatitis B vaccine (unknown manufacturer) and Prevenar. The event resolved after treatment with immunoglobulin.

- **B0693944A (Czech Republic): Thrombocytopenic purpura, Petechiae, Haematoma**

This case was reported by a physician via a regulatory authority (CZ-State Institute for Drug Control # CZ-CZSUKL-10002001) and described the occurrence of thrombocytopenic purpura in a 4-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevenar 13) for prophylaxis. The subject had no relevant medical history and no concomitant medication. On 10 December 2010, the subject received 2nd dose of Infanrix hexa (intramuscular, injection site unknown, batch number not provided) and 2nd dose of Prevenar 13 (intramuscular, injection site unknown, batch number not provided). On 11 December 2010, 1 day after vaccination with Infanrix hexa and Prevenar 13, the subject developed petechiae and small hematoma without any symptoms. On 13 December 2010, the subject was hospitalised for 3 days. The subject was diagnosed as having idiopathic thrombocytopenic purpura. Relevant test were performed on 13 December 2010 and showed platelets count of 4.5, APPT (activated partial prothrombine time) of 40.2, and INR (international normalized ratio) of 0.98. The subject was treated with infusion of normal immunoglobulin (Immunoglobulin). On 14 December 2010, the subject's status remained unchanged. On 16 December 2010, the subject was discharged from the hospital, recovering and with improved laboratory data. On 4 January 2011, the subject underwent follow-up examination. Blood count was normal, platelets count was 204 (normal value). At the time of

reporting, the events were resolved. The physician reported that the events were more likely related to vaccination with Infanrix hexa. He recommended any vaccination shouldn't be administered to the subject in next months. Despite attempts to obtain follow-up details, no additional information could be obtained and the case has been closed.

Company comment: A case of thrombocytopenic purpura suggestive of ITP in a 4 month-old male subject one day after second combined vaccination with Infanrix Hexa and Prevenar. The haematologic status recovered after intravenous immunoglobulin.

- **B0695999A (Taiwan): Thrombocytopenic purpura.**

This case described the occurrence of thrombocytopenic purpura in a 3-month-old subject of unspecified gender who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (DTPa-HBV-IPV-HIB, manufacturer unspecified) for prophylaxis. On 10 December 2007 the subject received 2nd dose of DTPa-HBV-IPV-HIB (unknown, lot number not provided). On 15 December 2007, 5 days after vaccination with DTPa-HBV-IPV-HIB, the subject experienced thrombocytopenic purpura. The subject was hospitalised. Relevant test results included platelet count: $2 \times 10^3/\text{mm}^3$ and hemoglobin: 8 g/dl. The subject was treated with normal immunoglobulin (Immunoglobulin). The event was resolved within 6 days. The author considered the event was possibly related to vaccination with DTPa-HBV-IPV-HIB. The event did not reoccur.

Company comment: A case of thrombocytic purpura 5 days after 2nd dose of Infanrix hexa in a 3-month-old subject. No autoimmune cause of this event was confirmed. No clear triggers or further episodes were reported.

- **B0724575A (France): Thrombocytopenic purpura, Thrombocytopenia, Petechiae, Injection site haematoma**

This case was reported by the French regulatory authority (FR-Agence Francais de Securite Sanitaire des Produits de Sante # PO20110384) and described the occurrence of thrombocytopenic purpura in a 19-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), mmr vaccine () (M-M-RvaxPro, non-gsk) for prophylaxis. Medical history included bronchiolitis and upper respiratory tract infection (NOS). On 01 March 2011, the subject received an unspecified dose of M-M-RVaxPro (intramuscular, batch and injection site unknown). On 26 April 2011, the subject received an unspecified dose of Infanrix hexa (intramuscular, batch and injection site unknown). After this vaccination, the subject presented a severe hematoma at injection site (that could be suggestive of a decrease of platelet count at this time). On 16 May 2011, the subject was hospitalized with diffuse cutaneomucous petechial purpura. He had no fever. Lab test evidenced a severe thrombocytopenia with decrease of platelet at 3 G/l (normal 150-400). The subject was treated with normal immunoglobulin (Tegeline). In 48 hours, platelet count increased to 64 G/l. Subject's discharge was planned for 18 May 2011. At the time of reporting, thrombocytopenia

was improved. Outcomes of hematoma at injection site and purpura, and petechiae were unspecified. According to the French method of assessment, the AFSSaPS considered the causal relationship between vaccination with Infanrix hexa and M-M-RvaxPro and the events as dubious.

Company comment: A case of thrombocytopenic purpura in a 19-month-old male subject 20 days after 2nd dose of Infanrix-hexa. No autoimmune cause of this event was confirmed. No clear triggers or further episodes were reported.

6.5.2.1.8. Thrombocytosis

Two (2) cases of Thrombocytosis were reported during the period:

- **B0729166A (Spain): Pemphigoid, Leukocytosis, Thrombocytosis, Blister, Scab, Skin lesion, Pruritus, Eosinophilia, Urticaria**

This case was reported in a literature article and described the occurrence of bullous pemphigoid in a 3-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (DTPa-HBV-IPV-HIB, manufacturer unspecified), meningococcal polysaccharide vaccine group C and unspecified Pneumococcal vaccine for prophylaxis. On an unspecified date, the subject received an unspecified dose of DTPa-HBV-IPV-HIB (administration site and route unknown, batch number not provided), an unspecified dose of Meningococcal polysaccharide vaccine group C (administration site and route unknown, batch number not provided) and an unspecified dose of Pneumococcal vaccine (administration site and route unknown, batch number not provided). 3 weeks after vaccination with DTPa-HBV-IPV-HIB, Meningococcal polysaccharide vaccine group C and Pneumococcal vaccine, the subject experienced bullous pemphigoid with blistering eruption on her palms and soles and back of the fingers, scabs and denuded areas and urticaria plaque on trunk and face. Subsequently, they were appearing lesions on the trunk, arms and andretroauricular region dominated by erythematous plaques of annular morphology. No mucosal involvement. The lesions were itchy and woke up the girl during the night. This case was assessed as medically serious by GSK. A skin biopsy was performed which showed a subepidermal blister with eosinophils and a few polymorphonuclears. In the superficial dermis, it was identified perivascular eosinophilic infiltrate. The direct immunofluorescence showed linear deposits of IgG and C3 in the epidermal basal membrane, with negativity for the markers IgA, IgM and C1q. Laboratory tests revealed leukocytosis with eosinophilia and thrombocytosis. Antibasement membrane antibodies and the rest of the profile of autoimmunity were negative. The subject was treated with antibiotics and steroid (Topical steroid) with a very good evolution and control of the lesions. After vaccination at 4 months-old, 3 to 4 days after vaccination, she presented a sudden worsening of the lesions, with involvement of palms, soles, trunk, arms and face in a generalized way. The subject was treated with deflazacort. 15 days after the start of the treatment, the lesions had completely disappeared in all locations. At the 6 months-old vaccination, in hours after vaccination, she experienced a slight outbreak, keeping the dose of corticosteroids orally. Later, there was a progressive decrease until its suppression at 3 months, no

relapse during 12 months of follow-up. After vaccination at 15 months-old, no AEs occurred. At the time of reporting, the events were resolved. The author considered the events were related to vaccination with DTPa-HBV-IPV-HIB, Meningococcal polysaccharide vaccine group C and Pneumococcal vaccine.

Company comment: A case of bullous pemphigoid 3 weeks after vaccination in a 3-month-old subject in childhood. Although there is a temporal relationship with repeat vaccinations at 4 and 6 months, it is difficult to determine a causal relationship.

- **D0072024A (Germany): Meningitis pneumococcal, Gastroenteritis rotavirus, Respiratory syncytial virus infection, Pneumococcal sepsis, Pharyngitis, Somnolence, Pyrexia, Fluid intake reduced, Respiration abnormal, Crying, Diarrhoea, Cardiovascular insufficiency, Pallor, Tachypnoea, Anaemia, Thrombocytosis**

See Section [6.5.2.7.11](#) Sepsis.

6.5.2.2. Cardiac disorders

6.5.2.2.1. Bradycardia

Eleven (11) cases including the event Bradycardia were identified during the period:

6.5.2.2.2. Cardiac arrest

Three (3) cases including the PT Cardiac arrest were reported during the period. Cases B0706503A and B0716780A are described in Section 6.5.1 Cases with a fatal outcome. The third case is described below:

- **D0069341A (Germany):** Circulatory collapse, Apnoea, Loss of consciousness, Pallor, Bradycardia, Salivary hypersecretion, Cyanosis, Epilepsy, Partial seizures, Foaming at mouth, Hypotonia, Cardiac arrest, Vomiting, Dyskinesia, Eye movement disorder, Productive cough, Depressed level of consciousness, Hypokinesia, Bronchitis

This case was reported by a physician and described the occurrence of collapse unspecified in a 3-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. On 5 November 2010 the subject received 2nd dose of Infanrix hexa (unknown route and application site). Approximately less than one hour after vaccination with Infanrix hexa, while being in the office yet, the subject experienced unspecified collapse. This case was assessed as medically serious by GSK. Follow-up was received by the physician on 10 December 2010, including a questionnaire. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer) Previous vaccination with Infanrix hexa and Prevenar 13 was well tolerated. On 5 November 2010 the subject received 2nd dose of Infanrix hexa (intramuscular, left thigh), together with unspecified dose of Prevenar 13 (intramuscular, right thigh). At an unspecified time after vaccination with Infanrix hexa and Prevenar 13, the subject experienced "abrupt pallor and hypopnoea/apnea for 3-4 minutes, short-time bradycardia for over 1 minute, salivation and loss of consciousness for 2-3 minutes". The subject was treated with oxygen. The subject was hospitalised for 2-4 days. At the time of reporting, on 9 November 2010, all events were resolved. The physician considered pallor, hypopnoea/apnea, short-time bradycardia, salivation and loss of consciousness were probably related to vaccination with Infanrix hexa and Prevenar 13. Follow-up was received from the reporting physician on 20 April 2011, including a questionnaire and 4 reports from other physicians. According to the questionnaire, there was no concurrent medical condition or any other risk factors. On an unspecified date the subject experienced cyanosis, apnea and bradycardia. These events were resolved after 3 minutes. The subject was treated with oxygen. At the time of reporting, all events were resolved. After the next vaccination with Infanrix hexa the events did not recur. The physician considered cyanosis, apnea and bradycardia were unrelated to vaccination with Infanrix hexa. "According to the physicians' reports, the suspicion of adverse events was not confirmed". According to the 1st physician's report from 17 December 2010, "suspected beginning generalized idiopathic epilepsy with unspecific epileptic seizures (atonic seizures with myoclonia) (possible epilepsy) was diagnosed. Secondary generalized epilepsy of focal origin (focal secondary epileptic convulsions) was considered by differential diagnosis. "Six weeks ago, after a vaccination, the subject experienced collapse with pallor, blue lips (cyanosis), foaming at mouth, unresponsive episode, atonia and loss of consciousness. These

events were resolved after 3 minutes. The subject was hospitalised and 48 hours observed. On discharge from hospital the subject was in normal condition. Electroencephalogram one week later showed normal findings. The events were interpreted as cardio-vascular phenomenon. Ultrasonic findings of heart showed small foramen ovale." It was reported that the subject experienced asystole lasting for 3 seconds. On 17 December 2010 the subject was vomiting. There was no fever. When the subject was laid down, the subject experienced pallor and blue lips. He experienced occasional jerking in head-shoulder area, salivation with forming of vesicles, loss of consciousness, unresponsiveness and eyes rolling. These events were resolved after approximately 5 minutes. Afterwards, the subject gradually came to himself, started crying and fell asleep. At the moment, the subject suffered from cough with mucus and was teething. The patient's family history included suspected benign infantile myoclonic epilepsy (the subject's brother). "Pregnancy anamnesis of subject's mother was without findings. After 40+2 weeks of pregnancy the subject was born, weighing 3750 g, with a size of 52 cm and an Apgar score of 9 / 10 / 10. The subject was healthy. Infant development was normal. There were no operations, no internal diseases, no special accidents. The subject was vaccinated only once, with the reported seizure. Despite that, there were no unusual findings." Electroencephalogram was performed and showed "sleep electroencephalogram according to age with well pronounced sleep architecture up to sleep phase C." "The subject now experienced his 2nd afebrile convulsive seizure with rather atypic progress. This time atonic with sprinkled myoclonia or cloni, trunk and head stressed, respectively. No relationship to a triggering situation or fever could be found, although the subject was suffering from phlegm and so suspicion of an infection associated seizure could not be ruled out completely." According to the 2nd physician's report from 3 January 2011, since the event on December 2010 there were no further events. Electroencephalogram was performed on 3 January 2011 and showed awake electroencephalogram according to age. Cerebral magnetic resonance tomography showed normal findings. "Immediately after electroencephalogram, the subject was atonic at trunk and extremities for 3-4 minutes, was pale and unusually calm. There was no fixed stare, but looking straight on, no indication for a focal event, no cloni. This was the 3rd event. It could possibly have been a seizure, too. Afterwards, there was no tiredness like after the former events." According to the 3rd physician's report from 11 April 2011, the subject visited the surgery on 17 February 2011. Sleep electroencephalogram was performed and showed normal findings. Concerning the Cerebral magnetic resonance tomography performed on 17 December 2010, "in the T2 assessed picture discrete signal increase in the area of white brain substance were conspicuous, which spread from the posterior horn rather diffuse". A second magnetic resonance tomography was recommended. It was reported that the subject's mother reported about mild motor retardation. According to the 4th physician's report, when the subject was 7 months old, there was no indication for structural abnormality of the heart, no indication of clinically relevant formation of a vascular ring. Affect spasm was considered by differential diagnosis. There were repeated incidents of loss of consciousness, at the 1st time at the age of 3 months after vaccination. A 2nd time after vomiting and 2 further times when expectorating mucus during bronchitis. There never was stridor. Electrocardiogram and echocardiography showed normal findings. Foramen ovale was functionally closed. "There was no indication of structural abnormality of the heart or anomaly in

the area of the great vessels. Especially there was no indication for pulmonal sling or arterial vascular ring, which could have been causal for such syncopal symptoms."

Company comment: Unspecified collapse in a 3 month-old female subject less than 1 hour after 2nd vaccination with Infanrix hexa, combined with Prevenar. Spontaneous recovery after 3 minutes with oxygen therapy. The event occurred 2 times more, unrelated to vaccinations. Suspicion of epileptic origin without conclusive results on EEG or MRI.

6.5.2.2.3. Cardio-respiratory arrest

One (1) case including the PT Cardio-respiratory arrest was received during the period (B0705290A) and is described in Section 6.5.1 Cases with a fatal outcome.

6.5.2.2.4. Cardiogenic shock

One (1) case including the PT Cardiogenic shock was reported during the period:

- **D0070772A (Germany): Cardiogenic shock, Cardiac failure, Congestive cardiomyopathy, Atrial tachycardia, Supraventricular tachycardia, Acidosis, Pyrexia, Gastrointestinal pain, Hypokalaemia, Fluid intake reduced, Hypertension, H1N1 influenza, Cholecystitis, Psychotic disorder, Crying**

This case was reported via a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011007870) and described the occurrence of cardiogenic shock in a 3-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa), live attenuated human rotavirus vaccine (Rotarix) and pneumococcal vaccines (non-gsk, Prevenar) for prophylaxis. Previous vaccinations were well tolerated. On 01 March 2011 the subject received a dose of Rotarix, a dose of Prevenar (right thigh) and a dose of Infanrix hexa (left thigh). According to the report Infanrix was administered, based on the provided lot number however it was evident that Infanrix hexa was administered. Twelve days after vaccination, on 13 March 2011, the subject developed atrial tachycardia and dilated cardiomyopathy. The following day, on 14 March 2011, cardiogenic shock occurred. The subject was hospitalised. Diagnosis was confirmed by means of laboratory examinations, ultra sound scan and electrocardiography (Results not specified). Meningitis was excluded. The reporter considered the events were life threatening. At the time of reporting the events were unresolved. Follow-up information was received on 26 April 2010 via the regulatory authority by means of structured information and a hospital report. On 01 March 2011 the subject received a dose of Infanrix hexa (left thigh) together with a dose of Prevenar (right thigh) and a dose of Rotarix. Twelve days after vaccination, on 13 March 2011, the subject presented at a hospital and suffered from reduced fluid intake, stomach pain and a mild increase in temperature (38.4 deg C). Cholecystitis was suspected and the subject was treated with claforan and ampicillin trihydrate. The subject's symptoms worsened continuously, tachycardia occurred (heart rate: 220-240 bpm) and the subject was in need of oxygen. The following day, on 14 March 2011 myocarditis was suspected and the subject was transferred to another hospital by helicopter. The subject was diagnosed with cardiogenic shock (with associated acidosis and arterial hypertension), received

artificial ventilation as well as an insertion of arterial and central venous catheters. In echocardiogram atrial enlargement and spherical ventricular dilation (left) were observed. Supraventricular tachycardia with alternating heart rates (occasionally above 220 bpm) was observed in electrocardiogram. For clarification of the origin of the subject's cardiac insufficiency, myocarditis was excluded by means of serologic findings. The subject was negative for cardiotropic infections. Cardiac muscular enzymes were borderline but normal. Antiarrhythmic therapy was started with propafenone hydrochloride (Rytmonorm), sotalol hydrochloride (Sotalex) and digoxin. Anticongestive therapy was started with enoximone (Perfan), frusemide (Furosemid), captopril and spironolactone (Aldactone). Additionally he was treated with teicoplanin (Targocid). Subsequently the subject's cardiac function improved and in echocardiogram ventricular dilation was found regressing. As myocarditis could be excluded, the subject was suspected with pre-existing focal atrial tachycardia and resulting heart insufficiency and current cardiogenic shock. Daily dose of antiarrhythmic medication was increased continuously. Heart rate was reduced significantly but continuous sine rhythm could not be established. Phases with extrasystoles were declining. At the hospital the subject was also observed with recurrent crying attacks and received treatment with sedatives (promethazine hydrochloride (Atosil) and phenobarbitone (Phenobarbital)). As there were no signs of pain or hunger, the subject's crying attacks were considered symptoms of transitory psychotic syndrome. On 18 March 2011 artificial ventilation was removed and the subject was observed with sufficient spontaneous respiration. The subject's general condition improved significantly and the subject could be switched to oral nutrition with supportive volume replacement. On 19 March 2011 pharyngeal swab was positive for H1N1 virus and treated with oseltamivir phosphate (Tamiflu) and meropenem (Meronem). In serologic examinations the subject was negative for Influenza A antibodies and positive for Influenza B IgG. The subject was also diagnosed with hypokalemia and received treatment with sodium fluoride (Zymafluor). After nine days the subject was discharged from the hospital. The regulatory authority reported that the subject was recovering.

Company comment: Cardiogenic shock in a 3 month-old male subject, 12 days after vaccination with Infanrix hexa, combined with Rotarix and Prevenar. Diagnosis of pre-existing focal atrial tachycardia and heart insufficiency recovered with anti-arritmica.

6.5.2.2.5. Cyanosis

Fifty eight (58) cases including the event cyanosis were identified during the period of this report. Most cases were reported in association with a concurrent disease likely to have caused cyanosis, as shown in [Table 8](#). Only one concurrent disease is shown per case, however more than one relevant concurrent disease may have been reported for a given case. This table also includes one case received prior to the period of this report but never included in a previous PSUR (B0591710A). This case's ID is marked by a '*' in [Table 8](#).

6.5.2.3. Eye disorders

6.5.2.3.1. Gaze palsy

Eighteen (18) cases including the event Gaze palsy were identified during the period of this report. In 12/18 cases the event was associated to a reported convulsion (febrile in 4 cases). The event lasted between 2 hours and 10 days by mean. The outcomes had been documented in half of cases and were favourable (resolved). Cases are summarized in the table below.

Table 9 Summary of cases of Gaze palsy identified during the period

6.5.2.4. Gastrointestinal disorders**6.5.2.4.1. Diarrhoea haemorrhagic**

Two (2) cases of Diarrhoea haemorrhagic were reported during the period:

- **B0747304A (Poland): Diarrhoea haemorrhagic, Pyrexia, Crying, Restlessness, Abnormal behaviour**

This case was reported by a physician via regulatory authority (PL-Office of Medicinal Products # -PL-URPL-OCR-20110905014) and described the occurrence of hemorrhagic diarrhea in a 4-month-old subject of unspecified gender who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), live attenuated human rotavirus vaccine (Rotarix) for prophylaxis. On 12 August 2011 the subject received unspecified dose of Infanrix hexa (intramuscular, unknown injection site), unspecified dose of Rotarix (oral). On 14 August 2011, 2 days after vaccination with Infanrix hexa and Rotarix, the subject experienced hemorrhagic diarrhea, fever (38 deg C) lasting for 2 days, crying, restlessness and change in behavior. Diarrhea withdrew after 11 hours. The subject was hospitalized from 14 to 18 August 2011. Relevant test results included: Rotavirus test: negative; Adenovirus test: negative; Salmonella test: negative; At the time of reporting the events were resolved. No further information is expected.

Company comment: The symptoms and test results confirming the diagnosis of digestive Haemorrhage (during 48 hours) after Infanrix hexa and Rotarix vaccination were not reported. Fever was associated to the episode but infectious cause could not be evidenced.

- **B0754698A (Poland): Diarrhoea haemorrhagic, Pyrexia, Vomiting, Faeces discoloured, Dermatitis diaper, Erythema, Dyspepsia**

This case was reported by a physician via a regulatory authority (PL-Office of Medicinal Products # PL-URPL-OCR-20110923001) and described the occurrence of bloody diarrhea in a 2-month-old subject of unspecified gender who was vaccinated with live attenuated human rotavirus vaccine (Rotarix, GlaxoSmithKline), combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa) and pneumococcal vaccines (non-GSK) (Prevenar 13) for prophylaxis. Since the 29 July 2009, the subject experienced restlessness. On 02 August 2011, during a medical visit, the subject had abdominal pain and inflated abdomen, which was decompressed with catheter. On 04 August 2011, during another medical visit, inflated abdomen decreased and it was also decompressed with catheter. On 10 August 2011, the baby was in good general condition, ultrasonography of the abdomen and urine cultures were without abnormalities. The subject had a soft belly. On 18 August 2011, the subject received unspecified dose of Rotarix (oral), unspecified dose of Infanrix hexa (intramuscular, unknown injection site), unspecified dose of Prevenar 13 (intramuscular, unknown injection site). On 19 August 2011, 1 day after vaccination with Infanrix hexa, Prevenar 13 and Rotarix, the subject experienced bloody diarrhea, fever (37.8 deg. C) and vomiting. The

subject was hospitalised. On 23 August 2011, at a medical control, the subject experienced dyspepsia, and still has stools with blood since a few days. On 24 August 2011, at the next medical control, the subject experienced diaper dermatitis, the stools became normal but severe reddening of skin on buttocks appeared. On 13 September 2011, the subject was hospitalised at Gastroenterological Clinic. At the time of reporting the outcome of the events was unspecified. No further information is expected, the regulatory Authority has provided GSK with all the available information for the time being, if they ever get any further information they will send it to GSK. Follow-up information received by the RAN: Hospitalisation dates were unclear so no clarification was possible. On 19 August 2011, the subject experienced green stools. On 24 August 2011, bloody diarrhea and green stools were resolved. The outcome of the rest of the events was unspecified.

Company comment: Episodes of haemorrhagic diarrhea in a 2-month-old subject starting 1 day after combined vaccination with Infanrix hexa, Priorix and Prevenar. The subject was hospitalized but diagnostic test results are not available. The event has been resolved.

6.5.2.4.2. Haematochezia

Three (3) cases of Haematochezia were reported over the period:

- **B0714317A (Czech Republic): Haematochezia, Gastrointestinal inflammation, Restlessness, Flatulence, Frequent bowel movements**

This case was reported by a physician and described the occurrence of blood streaks in stools in a 2-month-old female subject who was vaccinated with live attenuated human rotavirus vaccine (Rotarix, GlaxoSmithKline), combined diphtheria, tetanus-acellular pertussis, hepatitis B and inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa) for prophylaxis. The subject was healthy full term baby. On 23 March 2011, the subject received 1st dose of Rotarix (oral) and unspecified dose of Infanrix hexa (route and injection site unknown, batch number not provided). On 30 March 2011, 7 days after vaccination with Infanrix hexa and Rotarix, the subject experienced impurity of blood in stools, restlessness, flatulent belly and frequent stools. The physician considered the events were clinically significant (or requiring intervention). In April 2011, relevant test results included normal stool culture and normal sonography of abdomen which excluded intussusception. The subject was treated with symptomatic therapy. At the time of reporting, the events were unresolved. The physician considered the events were probably related to vaccination with Rotarix and the relationship between the events and Infanrix hexa was unspecified. Follow-up information received on 28 April 2011: The final diagnosis provided was unspecified gastrointestinal inflammation. The subject's condition was improved, but not resolved. Streaks of blood in stools appeared occasionally. Despite attempts to obtain follow-up details, no additional information could be obtained and the case has been closed.

Company comment: Intermittent haematochezia in a 2-month-old female subject starting 7 days after vaccination with Infanrix hexa and Rotarix. Final diagnosis of unspecified gastrointestinal inflammation after exclusion of infection and intussusception.

- **B0754377A (South Africa): Intussusception, Diarrhoea, Haematochezia**

This case was reported by a healthcare professional (nurse) and described the occurrence of intussusception in a 4-month-old female subject who was vaccinated with live attenuated human rotavirus vaccine (Rotarix, GlaxoSmithKline), combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa) and Synflorix for prophylaxis. The child was breastfeeding and was on formula. On 29 September 2011, the subject received unspecified dose of Rotarix (oral), unspecified dose of Infanrix hexa (unknown route of administration), unspecified dose of Synflorix (unknown route of administration). On 4 October 2011, 5 days after vaccination with Infanrix hexa, Rotarix and Synflorix, the subject experienced intussusception, diarrhea and blood in stools. The subject was seen by a paediatrician. This case was assessed as medically serious by GSK. On 5 October 2011, the subject was operated due to intussusception. At the time of reporting the outcome of the events was unspecified. The healthcare professional considered the events were possibly related to vaccination with Rotarix, Infanrix hexa and Synflorix.

Company comment: A bowel intussusception needing surgery in a 4-month-old female subject 5 days after combined vaccination with Infanrix hexa, Synflorix and Rotarix.

- **D0073097A (Germany): Haematochezia, Gastrointestinal pain**

This case was reported by a physician via a German regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011033460) and described the occurrence of blood in stools in a 13-week-old male subject who was vaccinated with live attenuated human rotavirus vaccine (Rotarix, GlaxoSmithKline) and combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma). The subject's past medical history was not provided. The subject has received no previous vaccination. On 29 September 2011 the subject received the first dose of Rotarix (0.5 ml, oral) as well as the first dose of Infanrix hexa (0.5 ml, intramuscular, left thigh) and the first dose of Prevenar 13 (0.5 ml, intramuscular, right thigh), contralaterally. Approximately two days post vaccination with Rotarix, Infanrix hexa and Prevenar 13, on 01 October 2011, the subject experienced blood in stools and gastrointestinal pain. The subject was hospitalised for an unknown period of time. Bacteria stool tests for Salmonella, Shigella, Yersinia and Campylobacter were negative. After about two days, on 02 October 2011, blood in stools was resolved. After about seven days, on 07 October 2011, gastrointestinal pain was resolved. The vaccination courses with Rotarix, Infanrix hexa and Prevenar 13 were discontinued. The German regulatory authority (DE-Paul-Ehrlich-Institut) has requested further information. At the moment no further information was available.

Company comment: Haematochezia 2 days after combined vaccination with Infanrix hexa, Rotarix and Rotarix in a 13-week-old male subject Infectious causes were

excluded and the event resolved spontaneously. Vaccination courses were discontinued.

6.5.2.4.3. Intussusception

One (1) case of Intussusception was reported during the period (B0754377A) and is described in Section 6.5.2.4.2 Haematochezia.

6.5.2.4.4. Rectal haemorrhage

One (1) case of Rectal haemorrhage was received during the period:

- **B0749250A (France): Rectal haemorrhage.**

This case was reported by a regulatory authority (Afssaps case ID # RS20110348) and described the occurrence of rectorrhagia in a 2-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and pneumococcal vaccines (Prevenar 13, non-gsk) for prophylaxis. Concurrent medical conditions included cow milk protein allergy with the following symptoms vomiting and bloating. The subject was fed with Neocate (hypoallergenic, amino-acid based, nutritionally complete infant formula). On 20 March 2011 the subject received a 1st dose of Infanrix hexa (intramuscular, batch and injection site unknown) and a 1st dose of Prevenar 13 (intramuscular, batch and injection site unknown). On 21 March 2011, 12 to 24 hours after vaccination with Infanrix hexa and Prevenar 13, the subject experienced rectorrhagia which persisted for 24 to 48 hours. One month later, rectorrhagia recurred. The regulatory authority reported that the event was clinically significant (or requiring intervention). At the time of reporting, rectorrhagia was resolved. According to the French method of assessment, the AFSSaPS considered unlikely the causal relationship between vaccination with Infanrix hexa and Prevenar 13 and rectorrhagia.

Company comment: 24 to 48 hours of rectorrhagia in a 2-month-old male subject 1 day after vaccination with Infanrix hexa and Prevenar. No details on symptoms, physical examination, investigations and treatment were reported. Recurrence after administration of another DTP-IPV-Hib (Pentavac, non GSK) 1 month later.

6.5.2.5. General disorders and administration site conditions

6.5.2.5.1. Abscess sterile, Injection site abscess sterile

Seven (7) cases of Abscess sterile/Injection site abscess sterile were received during the period and are summarized in [Table 10](#). Note that case **D0069239A (Germany): Soft tissue necrosis, Debridement, Incorrect route of drug administration** described a sterile abscess complication indicated for surgery and is reported in Section [6.5.2.8.2 Soft tissue necrosis](#).

6.5.2.5.3. Gait disturbance

During the period, 19 cases of Gait disturbance were received, out of which 8 serious. In almost all cases (18/19) the event described was associated with at least one other adverse event. The outcome was resolved for 14/19 of these cases and for 6/8 of the serious cases. In the other cases the outcome was unknown. These cases are summarised in [Table 12](#).

6.5.2.5.4. Injection site nodule

Twenty three (23) cases of Injection site nodule were received during the period, out of which 4 serious. The outcome was known as resolved or improved in 10/23 cases. These cases are summarised in [Table 13](#). This table also includes one case received prior to the period of this report but never included in a previous PSUR (B0637096A). This case's ID is marked by a '*' in [Table 13](#).

Table 13 Summary of cases of Injection site nodule identified during the period

6.5.2.5.5. Injection site urticaria

Three (3) cases of Injection site urticaria were received during the period (B0699204A, B0732577A and B0744335A). These cases are summarized in Section 6.5.2.11.7 Urticaria, Urticaria popular and Urticaria thermal.

6.5.2.5.6. Nodule

Three (3) cases of Nodule were received during the period:

- **B0701338A (France): Irritability, Sleep disorder, Pyrexia, Injection site induration, Nodule, Incorrect product storage**

This case was reported by a pharmacist and a physician and described an incorrect product storage in a 4-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Medical conditions and concurrent medications were unspecified. On 21 February 2011, the subject received a 3rd dose of Infanrix hexa (batch, route and injection site unknown). Before administration, the vaccine was stored at room temperature during 15 days (incorrect product storage) At the time of reporting, no adverse effect was reported. Upon follow-up received on 04 March 2011 from the pharmacist: The subject weighed 6.8 kg and measured 61 cm. On the same day, he received one dose of Infanrix hexa (batch A21CA584B) and one dose of pneumococcal vaccine (Prevenar, non-gsk, batch E16268) both stored at room temperature during 15 days. One week after vaccination, the subject experienced fever at 38.5-39 degrees Celsius, irritability with sleep disorder and presented at one vaccine injection site (vaccine unspecified) an induration. At the time of reporting, Infanrix hexa was not readministered. Outcome of events and the reporter's assessment were unspecified. Upon follow-up received from the physician on 13 May 2011: Infanrix hexa and Prevenar were administered intramuscularly in thigh. The physician noticed fever at 38 degrees Celsius, nodule and sleep disorder for 48 hours. On an unspecified date, Infanrix hexa was readministered without recurrence of events. The physician considered the causal relationship between Infanrix hexa and the reported events as almost certain.

Company comment: Injection site induration 1 week after 3rd vaccination with Infanrix hexa in a 4 month-old subject. The event resolved spontaneously.

- **B0726560A (Sweden): Nodule, Injection site extravasation, Abscess, Erythema**

This case was reported by a physician and described the occurrence of nodule in a 3-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Concurrent vaccination included pneumococcal vaccines (Prevenar 13) (non-GSK manufacturer, intramuscular, left thigh) given on 20 December 2010. In October 2010, the subject received 1st dose dose of Infanrix hexa (intramuscular, unknown injection site, lot number not provided). At an unspecified time after vaccination with Infanrix hexa, the subject experienced nodule. On 20 December 2010, the subject received 2nd

dose of Infanrix hexa (intramuscular, right thigh). At an unspecified time after vaccination with Infanrix hexa, the subject experienced an infiltrate with a size of a rice grain, which increased. In March 2011, 3 months after vaccination with Infanrix Hexan the subject experienced redness "like an abscess" which contained one table spoon of pus. At the time of reporting the outcome of the events was unspecified.

Company comment: Injection site nodule at unspecified time after vaccination with Infanrix hexa and Prevenar.

- **B0745840A (Italy): Injection site reaction, Nodule, Pyrexia**

This case was reported by a regulatory authority (IT-Agenzia Italiana del Farmaco # 147350) and described the occurrence of injection site reaction in a 6-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevenar 13) for prophylaxis. On 14 February 2011, the subject received 2nd dose of Infanrix hexa (intramuscular, site of injection unknown) and 2nd dose of Prevenar 13 (intramuscular, site of injection unknown). On 14 February 2011, less than one day after vaccination with Infanrix hexa and Prevenar 13, the subject experienced injection site reaction, nodule (unspecified site) and fever (39.5 Deg.C.). The subject was treated with paracetamol. On 16 February 2011, the events were resolved. Follow-up received on 18 October 2011: No further information was expected. This case is closed.

Company comment: Injection site reaction in a 6 month-old subject less than 1 day after 2nd injection with Infanrix hexa and Prevenar.

6.5.2.6. Immune system disorders

6.5.2.6.1. Anaphylactic shock

Three (3) cases of Anaphylactic shock were reported over the period. These cases are described below.

- **B0680987A (Belgium): Anaphylactic shock, Syncope, Apnoea, Bronchospasm, Blood pressure decreased, Pallor, Respiratory rate decreased, Crying, Hypoventilation**

This case was reported by a physician and described the occurrence of anaphylactic shock in a 2-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), rotavirus vaccine (non-gsk) (RotaTeq) and pneumococcal vaccines (non-gsk) (Prevenar) for prophylaxis. The subject had no concomitant disease and no concomitant medication. The subject had no previous reaction to drug or allergy. On 20 October 2010, the subject received first, 1st dose of RotaTeq (oral), and then unspecified dose of Infanrix hexa (intramuscular) and after unspecified dose of Prevenar (intramuscular). On 20 October 2010, 1 minute after vaccination with Prevenar, within minutes of vaccination with Infanrix hexa and Rotateq, the subject experienced anaphylactic shock, syncope, bronchospasm, decreased blood pressure,

pallor, respiration rate decreased, hypoventilation and possible apnea. The heart sounds were good. It took quite long before she fully recovered. She experienced no rash, no urticaria, no stridor and no wheezing. When the subject arrived at hospital, she was still pale but stable at cardio-respiratory level. No test was performed. The events lasted a few minutes. On 20 October 2010, the events were resolved, the subject had fully recovered. The physician considered the events were life threatening. The subject was treated with adrenaline (1mg/ml) 0,5 ml and 4 times respiration. The child's face brightened up and she started to cry. Her color came back and she breathed better again. But after 2 minutes, the baby became pale again. Again drowsy but recovered each time then began to cry again: was always so up and down. In the meantime ambulance was called. The subject was hospitalised for observation. At the time of reporting the events were resolved. The physician considered the events were almost certainly related to vaccination with Infanrix hexa, RotaTeq and Prevenar. This case has been identified as a duplicate of case B0685603A which was voided. This case was also reported by a physician via a sales representative.

Company comment: This 2-month-old female subject experienced anaphylactic reaction 1 minute after combined vaccination with Prevenar and within a few minutes after Infanrix hexa and RotaTeq (oral). This case fulfils Level 2 of diagnostic certainty of the Brighton Collaboration Anaphylaxis Working Group criteria.

- **B0741646A (Italy): Anaphylactic shock, Stridor, Respiratory disorder, Pulse pressure decreased, Heart rate increased, Crying**

This case was reported by a physician via a regulatory authority (IT-Agenzia Italiana del Farmaco # 146502) and described the occurrence of anaphylactic shock in a 2-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevenar 13) for prophylaxis. On 17 August 2011, the subject received 1st dose of Infanrix hexa (.5 ml, intramuscular, injection site unknown) and 1st dose of Prevenar 13 (.5 ml, intramuscular, injection site unknown). On 17 August 2011, less than one day after vaccination with Infanrix hexa and Prevenar 13, the subject experienced anaphylactic shock, slight laryngeal stridor, respiratory crisis, parvus and quick pulsus and weak weeping. The subject was hospitalised and the regulatory authority reported that the events were life threatening. The subject was treated with adrenaline, cardiac massage and oxygen. At the time of reporting, the events were improved. The regulatory authority reported that the events were possibly related to vaccination with Infanrix hexa and Prevenar 13.

Company comment: This 2-month-old female subject experienced anaphylactic reaction less than 1 day after combined vaccination with Prevenar and Infanrix hexa. This case fulfils Level 3 of diagnostic certainty of the Brighton Collaboration Anaphylaxis Working Group criteria.

- **D0071107A (Germany): Anaphylactic shock**

This case was reported by a physician and described the occurrence of anaphylactic shock in an 8-month-old male subject (born 20 April 2007) who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. On 10 January 2008 the subject received 2nd dose of Infanrix hexa (unknown route and injection site). At an unspecified time after vaccination with Infanrix hexa, the subject experienced anaphylactic shock. This case was assessed as medically serious by GSK. At the time of reporting the outcome of the event was unspecified. Despite of requests no further information will be available.

Company comment: This 8-month-old male subject experienced anaphylactic shock at an unspecified time after 2nd dose of Infanrix hexa. This report lacks important information such as anaphylaxis's symptoms, temporal sequence and treatment. This case fulfils Level 4 of diagnostic certainty of the Brighton Collaboration Anaphylaxis Working Group criteria.

6.5.2.6.2. **Anaphylactic/Anaphylactoid reaction and Drug hypersensitivity**

Four (4) cases of Anaphylactic reaction/Anaphylactoid reaction/Drug hypersensitivity were reported over the period:

- **B0698663A (Italy): Anaphylactic reaction, Circulatory collapse, Slow response to stimuli, Cyanosis, Hypotonia, Hypothermia, Pallor, Bradycardia, Oxygen saturation decreased, Pyrexia.**

This case was reported by a physician and described the occurrence of anaphylaxis reaction in a 4-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Concurrent medical conditions included premature birth at 24 weeks (birth weight 700 g). The subject was born by cesarean section at 24 weeks + 6 days. He underwent mechanical ventilation until 2 December 2010. The persistence of the opening of the duct of Botallo was treated with cycles of ibuprofen and indomethacin, the ductus closed on 4 December 2010. The broncodysplasia of lung was treated with cortisone cycles and at the time of vaccination the subject was in good condition. Vaccinations ran the next in a protected environment. The medical family history included allergic reaction with Quincke's oedema due to cephalosporin (mother) and allergy to Novalgina (grandfather). Concurrent vaccination included respiratory syncytial virus vaccine (manufacturer unspecified; route and injection site unknown) given on an unspecified date. In February 2011, prior to the discharged, the subject received unspecified dose of Infanrix hexa (route and injection site unknown, batch number not provided). In February 2011, less than one day after vaccination with Infanrix hexa, the subject experienced collapse, hyporesponsiveness, hypotonia nos and hypothermia. The subject was hospitalised. Tests were performed and showed normal results. At the time of reporting, the events were resolved. The physician considered the events were possibly related to vaccination with Infanrix hexa. Follow-up information reported by a physician via a

regulatory authority (IT-Agenzia Italiana del Farmaco # 134734): Concurrent medications included Palivizumab (Synagis), Frusemide (Lasix), Iron polymaltose (Intrafer), Multivitamins (Idroplurivit), Nutritional supplement (Reuterin) and Emollient (Folium). The subject was vaccinated with Infanrix hexa on 1st February 2011 (intramuscular, injection site unknown). On 1st February 2011, less than 1 day after vaccination with Infanrix hexa, the subject also developed pallid cyanosis, bradycardia, desaturation, fever and anaphylaxis reaction. On 2 February 2011, the events were resolved. Relevant tests were performed: an electrocardiogram was performed on 1st February 2011, X-ray, X-ray of the skull and C-reactive protein were performed on 2nd February 2011 and on 3rd February 2011, an electroencephalogram was performed. All these investigations showed normal results. The regulatory authority reported that the events were possibly related to vaccination with Infanrix hexa.

Company comment: This 4-month-old male subject with a history of premature birth (24 weeks) experienced anaphylactic reaction less than 1 day after vaccination with Infanrix hexa. This case fulfils Level 4 of diagnostic certainty of the Brighton Collaboration Anaphylaxis Working Group criteria.

- **D0072050A (Germany): Anaphylactic reaction, Swelling, Erythema, Crying, Petechiae**

This case was reported by a physician via a sales representative and described the occurrence of anaphylactic reaction in a 3-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccination included pneumococcal vaccines (non-gsk) (Prevenar 13, Pfizer). On 12 July 2011 the subject received unspecified dose of Infanrix hexa (unknown route, unknown thigh) given contralaterally to unspecified dose of Prevenar 13 (unknown route, unknown thigh). On 12 July 2011, shortly after vaccination with Infanrix hexa and Prevenar 13, the subject experienced severe swelling with erythema on both legs up to groin. He was crying more than normal. The physician diagnosed anaphylactic reaction with swelling on both legs. The subject was hospitalised. At the time of reporting the outcome of the events was unspecified. The physician also informed German regulatory authority (Paul-Ehrlich-Institute) and public health agency. Written follow-up information was received on 22 July 2011 from physician. On 12 July 2011 the subject received 1st dose of Infanrix hexa (intramuscular, left thigh) and 1st dose of Prevenar 13 (intramuscular, right thigh). On 12 July 2011, less than one day after vaccination with Infanrix hexa and Prevenar 13, the subject experienced extensive swelling at both extremities and erythema. He was crying more than normal. On 13 July 2011, the subject developed petechiae. Anaphylactic reaction was not mentioned anymore. The subject was hospitalised. The subject was treated with cooling and prednisone (Rectodelt). On 12 July 2011, abnormal crying was resolved. On 13 July 2011, swelling was resolved and erythema improved. No outcome for petechiae was reported, but event lasted until 18 July 2011. The vaccination course with Infanrix hexa was discontinued. The physician considered swelling; erythema and crying were almost certainly related to vaccination with Infanrix hexa and Prevenar 13. Written follow-up information was received on 08

August 2011 from Paul-Ehrlich-Institut (# DE-PEI-PEI2011025401) with no new medical information. No further information will be available.

Company comment: This 3-month-old male subject experienced a suspect anaphylactic reaction after 1st dose of Infanrix hexa. This case fulfils Level 5 of diagnostic certainty of the Brighton Collaboration Anaphylaxis Working Group criteria.

- **D0072500A (Germany): Anaphylactoid reaction, Hypersensitivity, Product quality issue, Urticaria, Rash, Apathy, Anaphylactic reaction, Erythema, Petechiae, Injection site erythema.**

This case was initially reported by a pharmacist and described the occurrence of anaphylactoid reaction in a 13-week-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. The case was also received as pharmaceutical product complaint. On an unspecified date the subject received an unspecified dose of Infanrix hexa (0.5 ml, unknown). At an unspecified time post vaccination with Infanrix hexa, on an unknown date, the subject experienced severe allergic reaction. At the time of reporting the outcome of the event was unspecified. Follow-up information was received on 26 August 2011 from the quality assurance department. The event was now reported as anaphylactoid reaction. Follow-up information was received on 02 September 2011 from the quality assurance department. Based on all available data it was concluded that there was no evidence for a specific safety signal for the used lot of Infanrix hexa. Follow-up information was received on 16 September 2011 from the quality control department. All received returned samples conform to the description specifications. Based on QC results the pharmaceutical product complaint was considered to be unsubstantiated. Follow-up information from the reporting pharmacist has been requested. Follow-up information was received on 20 October 2011 from the vaccination responsible physician. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma). On an unknown date in 2011 the subject received the first dose of Infanrix hexa (0.5 ml, unknown) and the first dose of Prevenar 13 (0.5 ml, unknown). At an unspecified time post vaccination with Infanrix hexa, on an unknown date, the subject experienced anaphylactoid reaction. The subject was hospitalised for an unknown period of time. At the time of reporting the outcome of anaphylactoid reaction was unspecified. The vaccination responsible physician considered that anaphylactoid reaction may be causally related to vaccination with Infanrix hexa and/or Prevenar 13. Follow-up information including a hospital report was received on 25 October 2011 from a physician. For the first time age and gender of the subject have been reported. The subject has no underlying or concurrent medical conditions or other risk factors. Previous vaccination with the first doses of combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma), given on 15 June 2011, was well tolerated. On 24 August 2011 at around 11:00 the subject received the second dose of Infanrix hexa (0.5 ml, unknown, unknown thigh) and the second dose of Prevenar 13 (0.5 ml,

unknown, unknown thigh). Approximately 5 - 7 minutes post vaccination with Infanrix hexa and Prevenar 13, on 24 August 2011, the subject experienced generalized urticaria with apathy. The subject did not experience dyspnea or hypotension. According to the reporting physician these events were resolved after about four hours. The physician reported that the same batches of Infanrix hexa and Prevenar 13 had been used when the subject had received the first doses of Infanrix hexa and Prevenar 13 on 15 June 2011. On 24 August 2011 the subject was hospitalised for two days at a pediatric clinic for possible anaphylaxis post vaccination with the second doses of Infanrix hexa and Prevenar 13. According to anamnesis in the hospital the subject experienced urticaria at the head approximately 5 - 10 minutes post vaccination with Infanrix hexa and Prevenar 13, on 24 August 2011. Urticaria spread quickly over the whole body. But at the extremities the subject experienced mild exanthema (exanthema on extremities). An ambulance was called. The subject was transported to the pediatric clinic without complications. All previous vaccinations with not further specified vaccines have been well tolerated. As a neonate the subject received phototherapy for hyperbilirubinemia. One week prior to vaccination with the second doses of Infanrix hexa and Prevenar 13, on an unknown date in August 2011, the subject had suffered from rhinitis without fever. On 25 August 2011 the subject was discharged in good general condition with completely resolved urticaria for ambulatory follow-up. At the time of discharge from hospital the subject showed injection site redness. No further information will be available.

Company comment: This 13-week-old male subject experienced approximately 5 - 7 minutes after 1st vaccination with Infanrix hexa and Prevenar, generalized urticaria with apathy considered causally related to the vaccination. The subject did not experience anaphylaxis (dyspnea or hypotension). The case was also received as pharmaceutical product complaint and it was concluded that there was no evidence for a specific safety signal for the used lot of Infanrix hexa. This case fulfils Level 5 of diagnostic certainty of the Brighton Collaboration Anaphylaxis Working Group criteria.

- **B0712429A (Czech Republic): Salmonella sepsis, Rash generalised, Pyrexia, Diarrhoea, Drug hypersensitivity, Hypersensitivity**

This case was reported by a physician and described the occurrence of salmonella enteritidis sepsis in a 7-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) and synflorix for prophylaxis. Since 12 December 2010, she was treated with Budesonide. Previous and/or concurrent vaccination included combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. ;GlaxoSmithKline;unknown;unknown given on 27 January 2011; synflorix ;GlaxoSmithKline;unknown;unknown given on 27 January 2011. No reactions after the 1st dose. Concurrent medications included Budesonide (Budiar). On 1 March 2011, the subject received 2nd dose of Infanrix hexa (administration site and route unknown), 2nd dose of Synflorix (administration site and route unknown). On 1 March 2011, less than one day after vaccination with Infanrix hexa and Synflorix, the subject experienced fever (39.4 deg.C). On 2 March

CONFIDENTIAL

CONFIDENTIAL

2011, 1 day after vaccination with Infanrix hexa and Synflorix, the subject experienced generalised exanthema on the whole body, generalised allergic reaction and diarrhea. The subject was hospitalised for 13 days, from 2 to 14 March 2011. Blood tests were performed and showed pathological results: C-reactive protein: 8.3 mg/l and leucocytes: 27 Giga/l. The subject was treated with dimethindene maleate (Fenistil), prednisone (Prednison), and ibuprofen (Nurofen). After next dose of Nurofen, the exanthema repeated and worsened. An allergic reaction to Nurofen was diagnosed. On 6 March 2011, the diarrhea continued. She was afebrile and exanthema recovered. A microbiological cultivation of stool showed *Salmonella enteritidis* and on second blood tests, leucocytes was 33 Giga/l and c-reactive protein :121mg/l. The subject was admitted to Intensive Care Unit with the diagnosis of salmonellosis sepsis. She was treated with gentamicin sulphate (Gentamycin) and cefotaxime (Cefotaxim). On 14 March 2011, C-reactive protein was 6 mg/l. On 14 March 2011, salmonella enteritidis sepsis was resolved. Follow-up information received on 15 April 2011: Concurrent medical conditions included recurrent obstructive bronchitis since 3 months of age, but allergy had not been proved. As no additional information could be obtained, the case has been closed.

Company comment: This 7-month-old female subject experienced generalised allergic reaction (exanthema) and diarrhea 1 day after vaccination with Infanrix hexa and Synflorix. A concomitant Salmonella enteritis infection could have play a trigger role in the drug hypersensitivity.

6.5.2.7. Infections and infestations

6.5.2.7.1. Abscess, Abscess limb, Incision site abscess, Injection site abscess, Injection site infection, Streptococcal abscess

During the reporting period, 25 cases were received including one of the following MedDRA Preferred Terms: Abscess (n=10), Abscess limb (n=1), Incision site abscess (n=2), Injection site abscess (n=12), Injection site infection (n=2), Streptococcal abscess (n=2). These cases are summarised in [Table 14](#).

Table 14 Summary of Abscess-related cases received during the period

6.5.2.7.2. Cellulitis

Two (2) cases of Cellulitis were received during the period:

- **B0713564A (Serbia): Cellulitis, Erythema, Body temperature increased, Injection site swelling**

This case was reported by a physician and described the occurrence of phlegmon in a 2-year-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Previous and/or concurrent vaccination included combined diphtheria, tetanus, acellular pertussis, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (GlaxoSmithKline) given on an unspecified date. No adverse events occurred after the 2 doses. Concurrent medical conditions included weak immune system. Due to this, the administration of the 3rd dose was postponed up to date. On 8 April 2011, the subject received 3rd dose of Infanrix hexa (intramuscular, unknown thigh, batch number not provided). On 10 April 2011, 2 days after vaccination with Infanrix hexa, the subject experienced intensive erythema, increased in local temperature and swelling injection site (10 cm diameter) above skin level. The subject was hospitalised and the diagnosis of phlegmon was made. No surgery was performed. He was treated with pharmacotherapy only. The subject was treated with ceftriaxone and antibiotics (Antibiotic). At the time of reporting, the events were unresolved, he was still in hospital. At the time of reporting, no additional data were available regarding his condition. Follow-up information received on 15 July 2011: As no additional information could be obtained, the case has been closed.

Company comment: Phlegmon in a 2 year-old male subject 2 days after 3rd vaccination with Infanrix hexa. The subject was hospitalized and treated with antibiotics. The subject had a weak immunesystem (not further specified).

- **B0730177A (Spain): Cellulitis, Streptococcal bacteraemia, Local reaction, Pyrexia**

This case was reported by a regulatory authority (ES-Agencia Esp de Medicamentos y Prod Sanitarios # ES-AGEMED-224093441) and described the occurrence of cellulitis in a 9-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) for prophylaxis. On 22 February 2011, the subject received an unspecified dose of Infanrix hexa (intramuscular, administration site unknown). On 1 March 2011, 7 days after vaccination with Infanrix hexa, the subject experienced fever. On 3 March 2011, 9 days after vaccination with Infanrix hexa, the subject experienced local reaction in lower limbs and cellulitis. On 5 March 2011, 11 days after vaccination with Infanrix hexa, the subject experienced streptococcal bacteremia. The subject was hospitalised from 5 to 16 March 2011 and the regulatory authority reported that the events were clinically significant (or requiring intervention). The diagnosis was cellulitis due to streptococcal bacteremia. The subject was treated with ibuprofen and antibiotics (Antibiotic). On 16 March 2011, cellulitis, streptococcal bacteremia and local reaction were resolved. In March 2011, fever was resolved. The regulatory

CONFIDENTIAL

CONFIDENTIAL

authority reported that the events were probably related to vaccination with Infanrix hexa.

Company comment: Cellulitis in lower limbs and streptococcal bacteremia 9 days after vaccination with Infanrix hexa in a 9-month-old subject. The timeframe between injection and cellulitis seems long for a causal relationship. There is no other information about other possible sources of infection.

6.5.2.7.3. Encephalic infection

One (1) case of Encephalitic infection was received during the period (B0692285A) and is described in Section [6.5.2.9.5](#) Encephalitis, Encephalopathy and Encephalic infection.

6.5.2.7.4. Injection site cellulitis

Two (2) non-serious cases of Injection site cellulitis were received during the period and are summarized in [Table 15](#).

Table 15 Summary of cases of Injection site cellulitis received during the period

Case ID	Initial Date Received By Dept	Case Outcome	Age	Gender	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Events PT Comma Sep	Country Of Reporter	Medical Conditions PT Comma
B0747623A	14-Sep-11	Unknown	6 Months	Male	Infanrix hexa		Unknown	Injection site cellulitis, Extensive swelling of vaccinated limb, Injection site oedema	Belgium	Multiple allergies
B0748879A	16-Sep-11	Unresolved	16 Months	Male	Infanrix hexa		1 Days	Injection site cellulitis, Injection site warmth, Injection site pain, Inflammation, Hypersensitivity, Injection site swelling, Injection site erythema, Injection site induration	Belgium	

6.5.2.7.5. Meningitis aseptic

One (1) case of Meningitis aseptic was reported during the period:

- **B0714940A (France): Meningitis aseptic**

This case was reported by the French regulatory authority (AFSSaPS number MA20110871) and described the occurrence of lymphocytic meningitis in a 4-month-old female subject who was vaccinated with combined diphtheria, tetanus, acellular pertussis, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrixquinta, GlaxoSmithKline) for prophylaxis. Medical history and concurrent medications, if any, were unspecified. On 26 March 2011, the subject received 2nd dose of Infanrixquinta (intramuscular, unknown injection site, batch number "121CD021B" as reported and A21CB021B according to sales data). On 30 or 31 March 2011 (inconsistent information), four or five days after vaccination with Infanrixquinta, the subject experienced lymphocytic meningitis. On 03 April 2011, she was transferred to the intensive care unit. Analysis of nasal sample found PCR positive for Enterovirus. After symptomatic therapy, the subject's condition improved. Hospitalisation in intensive care unit lasted five days. The AFSSaPS reported that the event was life threatening. At the time of reporting the event was resolved without sequelae. The AFSSaPS considered the relationship between the event and the vaccination with Infanrixquinta was dubious, according to the French method of assessment. Upon follow-up received from the french center of pharmacovigilance on 09 May 2011: Suspect drug was changed to Infanrix hexa, the reporter confirmed the batch number but the name of the vaccine was unreadable on the vaccines record. Upon follow-up received from AFSSAPS on 16 May 2011: AFSSAPS had made the change from Infanrix Quinta to Infanrix Hexa on their database, as previously reported.

Company comment: Lymphocytic meningitis in a 4 month-old female subject 4 or 5 days after vaccination with Infanrix hexa. The subject was hospitalized and the event recovered with symptomatic therapy. There is no additional information about investigation of other sources of infection. The AFSSaPS considered the relationship between the event and the vaccination dubious, according to the French method of assessment.

6.5.2.7.6. Meningitis pneumococcal

Two (2) cases of Meningitis pneumococcal were received during the period:

- **D0069889A (Germany) Meningitis pneumococcal, Grand mal convulsion, Epilepsy, Hydrocephalus, Subdural hygroma, Subdural empyema, Anaemia, Generalised oedema, Ileus paralytic, Conjunctivitis, Septic shock, Pneumonia primary atypical, Neurosurgery, Pyrexia, Abdominal distension, Ill-defined disorder, Restlessness, Hyperaesthesia, Oligodipsia, Eye movement disorder, Hypertonia, Tachycardia, Oxygen saturation decreased, Ascites, Respiratory arrest, Drug ineffective, Cyanosis, Splenomegaly**

This case was reported by a physician and described the occurrence of pneumococcal meningitis in a 4-month-old male subject who was vaccinated with combined

diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccines included 13-valent pneumococcal vaccines (non-gsk) (Prevenar 13, Pfizer) and rotavirus vaccine (non-gsk) (RotaTeq). The subject's medical history included premature birth at 36 weeks of gestation and congenital bacterial pneumonia (with sterile throat smear, abdominal aspirate and blood culture). The subject was healthy on the day of vaccination. On 1 October 2010 the subject received unspecified dose of Infanrix hexa (unknown route and application site), unspecified dose of Prevenar 13 (unknown route and application site) and unspecified dose of RotaTeq (oral). On 04 October 2010 the subject had increased body temperature (over 40 degC). A physician was consulted the next day, but clinical examination was without pathologic findings, except for abdominal distension. There were no neurological findings. The subject was treated with unspecified antipyretic measures. On 06 October 2010 the physician was again consulted with fever up to 40.5 degC and the patient was whining, whimpered, was restless, touch-sensitive and the drinking volume was reduced. After a short examination the subject began to seize. No drugs were administered. The subject had tonic seizures of all limbs, light-fixed pupils and open eyes with ocular deviation to top left. The subject was hospitalised on 06 October 2010 in reduced general condition with grand mal seizure and meningitis. The physician considered the events were life threatening and clinically significant (or requiring intervention). The subject showed convex, pulsating fontanel with a size of 3x4 cm, muscle hypertonus, positive meningitic signs (meningism, Laegue, Brudzinski and Kernig), tachycardia and distended abdomen. Bacterial meningitis was suspected. The patient was treated with sodium chloride and cefotaxime (Cefotaxim), phenobarbitone (Phenobarbital), oxybate sodium (Somsanit) for sedation. After the subject slept, seizures ceased. Lumbar puncture showed increased lumbar pressure and murky cerebrospinal fluid (CSF) with S. pneumoniae in rapid test. Treatment with cefotaxime (Cefotaxim), phenobarbitone (Phenobarbital), gentamicin sulphate (Gentamycin), dexamethasone and dipyrone (Metamizole sodium) was started. On 07 October 2010 the fever resolved and the patient drank well. Because of reduced stool excretion, the subject received frusemide (Lasix) for expulsion, simethicone (Sab simplex) and hyoscine butylbromide (Buscopan). Because of reduced oxygen saturation (87%) the subject received oxygen. Anemia was treated with Red blood cell concentrate. The patient's condition improved with stable oxygen saturation and good urine expulsion. On 08 October 2010 the subject showed impaired condition, reduced drinking volume, unchanged fontanel, negative pupil reaction, sensitivity to touch, restlessness and increasing abdominal tension. Abdominal sonogram showed ascites, treated with frusemide. Because of still high readiness for seizures, lumbar puncture was performed. Lumbar pressure was normal. Cerebrospinal fluid test showed Streptococcus pneumoniae. Inflammatory parameters (C-reactive protein (CRP) and white blood cell count) were increased. Treatment was changed to vancomycin and cefotaxime. The subject drank better and became calm. On 09 October 2010 the subject received bladder catheter and intestinal tube due to intestinal paralysis. On 11 October 2010 bladder catheter was removed and the dose of Phenobarbital reduced. The subject drank normally, but had thin stool. Physiotherapy was started. Within the next days the subject's condition improved and treatment drugs could be reduced. Additional treatment included escherichia coli (Mutaflor). On 14 October 2010 the

subject developed conjunctivitis and was treated with benzalkonium chloride, ofloxacin (Floxal) and later with colistin and erythromycin lactobromide (Ecolicin). Restlessness was treated successfully with promethazine hydrochloride (Atosil). Because of cough, increased inflammatory parameters and increased body temperature, an X-ray was performed, which showed atypical pneumonia. On 18 October 2010 the subject had another tonic-clonic, generalised seizure with perioral fasciculation and breathing pause. Diazepam was without effect. After treatment with Phenobarbital the seizure ceased. Cranial sonogram showed extended inner and outer subarachnoid spaces. The subject was transferred to another hospital with the suspect of subdural empyema. Diagnoses in hospital included pneumococcal meningitis, symptomatic epilepsy, decreased cerebrospinal fluid resorption (hydrocephalus), generalized edema, septic shock and drug ineffectiveness. Magnetic resonance imaging (MRI) showed subdural hygroma and subdural empyema, at the right side more than at the left. The subject was treated with anti-epileptic medication and neurosurgical operation. On 18 October 2010 the subject underwent subdural-peritoneal shunt implantation. Epilepsy still required treatment. The reporting physician considered the events were probably related to Prevenar 13. Follow-up information was received on 21 January 2011 via Pfizer. The reporting physician stated that the result of serotype analysis was unknown. The following events were still unresolved: pneumococcal meningitis, epilepsy, hydrocephalus, subdural hygroma. The outcome of the following events was unknown to the physician: Grand mal attacks, subdural empyema, anaemia, edema, paralytic intestine, conjunctivitis, septic shock and pneumonia. The reporting physician considered the events were possibly related to Prevenar 13. Follow-up information was received on 16 May 2011 via Pfizer. The subject had no immunodeficiency. It was the first dose of Prevenar 13 (intramuscular) and Infanrix hexa and the third dose of RotaTeq. The reporter of this follow-up considered pneumococcal meningitis was unlikely related to Prevenar 13. A hospital report was provided, with similar information to the initial report. When admitted to hospital, the subject also showed peripheral cyanosis. Sonogram on 08 October 2010 also showed splenomegaly. According to follow-up information from 20 May 2011 pneumococcal meningitis was caused by streptococcus pneumonia serotype 19A.

Company comment: Pneumococcal meningitis in a 4-month-old male subject 5 days after first dose of Infanrix hexa and Prevenar third dose of RotaTeq. The subject required subdural-peritoneal shunt implantation due to ineffective antibiotic therapy. The outcome of sequellae (grand mal attacks) is unknown.

- **D0072024A (Germany) Meningitis pneumococcal, Gastroenteritis rotavirus, Respiratory syncytial virus infection, Pneumococcal sepsis, Pharyngitis, Somnolence, Pyrexia, Fluid intake reduced, Respiration abnormal, Crying, Diarrhoea, Cardiovascular insufficiency, Pallor, Tachypnoea, Anaemia, Thrombocytosis**

This case was reported by a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011022521) and described the occurrence of pneumococcal meningitis with sepsis in a 3-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-

suspect vaccination included 13-valent pneumococcal vaccine (non-GSK) (Prevenar 13, Pfizer). First vaccination with both vaccines was received on 13 April 2011. On 24 May 2011 the subject received 2nd dose of Infanrix hexa (intramuscular, right thigh), 2nd dose of Prevenar 13 (intramuscular, left thigh). On 25 May 2011, less than one day after vaccination with Infanrix hexa and Prevenar 13, the subject experienced pneumococcal meningitis with pneumococcal sepsis, rotavirus gastroenteritis and respiratory syncytial viral infection. The events were resolved after 14 days. The subject was hospitalised for 15 days and the events were life threatening. A hospital report was provided. The subject was hospitalised from 25 May to 08 June 2011. According to the report, the subject developed sleepiness, high fever and fluid intake reduced on the day of admission. An ambulance was consulted, where the subject showed abnormal respiration, crying and stinky, green diarrhea. When admitted to hospital the subject additionally showed circulatory depression and pale lips, as well as enteric bowel sounds. Oxygen saturation was good. After treatment with sodium chloride (NaCl) the condition improved, but worsened again in the evening, with tachypnea. Cerebrospinal fluid test showed bacterial meningitis and the subject was treated with cefotaxime (Cefotaxim) and gentamicin sulphate (Gentamycin). The subject was transferred to an intensive care unit. The next 24 hours of monitoring were uneventful. Additional treatment included dipyrone (Novalgin), paracetamol and further fluid. Cerebrospinal fluid, blood test and throat swab showed masses of *Streptococcus pneumoniae*. Rotavirus in stool and respiratory syncytial virus (RSV) in swab were positive. Inflammatory parameters were transiently increased. The subject had mild anemia and thrombocytosis, which were considered to be triggered by infection. Additionally the subject was diagnosed with pharyngitis. On 27 May 2011 fever resolved and on the next day the subject was transferred back to a normal unit. Further course was without complications and with continuous improvement. On 08 June 2011 the subject was discharged in good general condition. No further information will be available.

Company comment: Less than one day after combined vaccination with Infanrix hexa and Prevenar, this 3-month-old male subject experienced pneumococcal meningitis with sepsis. The subject recovered after 14 days of hospitalisation and parenteral antibiotherapy.

6.5.2.7.7. Meningitis viral

One (1) case of Meningitis viral was received during the period and is described in Section 6.5.1 Cases with a fatal outcome.

6.5.2.7.8. Osteomyelitis

One (1) case of Osteomyelitis was received during the period:

- **D0069814A (Germany): Osteomyelitis, Bone abscess.**

This case was reported by a physician and described the occurrence of osteomyelitis in a 9-week-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and *Haemophilus influenzae*

type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. On 29 October 2010 the subject received the first dose of Infanrix hexa (0.5 ml, unknown). Approximately six days post vaccination with Infanrix hexa, on 04 November 2010, the subject experienced osteomyelitis. The event was reported by the subject's father. The subject was hospitalised for 22 days from 12 November 2010 to 03 December 2010. At the time of reporting, on 21 December 2010, the outcome of the event was unspecified. Follow-up information was received on 04 January 2011 from the reporting physician. The subject has no underlying or concurrent medical conditions or other risk factors. The subject has received no previous vaccinations. On 29 October 2010 the subject received the first dose of Infanrix hexa (0.5 ml, intramuscular, right thigh). Approximately six days post vaccination with Infanrix hexa, on 04 November 2010, the subject experienced fractured femur left distal. Treatment included immobilising by plaster cast. Approximately 15 days post vaccination with Infanrix hexa, on 13 November 2010, the subject was diagnosed with osteomyelitis left at tibia metaphysic left medial with periosteal abscess. The subject was hospitalised on 12 November 2010 for surgery. Treatment included opening and draining of the abscess on 12 November 2010. At the time of follow-up reporting all events were resolved but control examinations have to be performed to exclude sequelae. The vaccination course with Infanrix hexa was discontinued. No further information will be available from the reporting physician. The same case was received on 21 July 2011 from the German regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2010038778).

Company comment: This 9-week-old male subject experienced osteomyelitis with bone abscess two weeks after 1st dose of Infanrix hexa. The subject had a left distal femur fracture 6 days post-vaccination and developed osteomyelitis at tibia metaphysic left medial with periosteal abscess (bone abscess) 14 days post-vaccination. The patient was hospitalised and treated surgically. All events have been resolved and control examinations are performed to exclude sequelae

6.5.2.7.9. Pneumococcal sepsis

One (1) case of Pneumococcal sepsis was received during the period (D0072024A) and is described in Section 6.5.2.7.6 Meningitis pneumococcal.

6.5.2.7.10. Salmonella sepsis

One (1) case of Salmonella sepsis was received during the period (B0712429A) and is described in Section 6.5.2.6.2 Anaphylactic/Anaphylactoid reaction and Drug hypersensitivity.

6.5.2.7.11. Sepsis

Four (4) cases of Sepsis were received during the period:

- **B0700040A (Sweden): Meningitis, Sepsis, Shock, Pneumococcal infection, Renal impairment, Hepatic function abnormal, Pyrexia, Diarrhea, Vomiting**

See Section 6.5.1 Cases with a fatal outcome.

- **D0069502A (Germany): Oedema peripheral, Sepsis, Swelling, Erythema**

This case was reported by a physician via a sales representative and described the occurrence of bilateral leg swelling in a 20-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and 10 valent pneumococcal conjugate vaccine (Synflorix, GlaxoSmithKline) for prophylaxis. Concurrent medical conditions included ocular neoplasm. Concurrent medications included treatment with ketamine (Ketanest) three days prior to vaccination with Infanrix hexa and Synflorix, on 08 November 2010. Previous vaccinations had been performed by another paediatrician. On 11 November 2010 the subject received the fourth dose of Infanrix hexa (0.5 ml, intramuscular, unknown application site at left side) and the fourth dose of Synflorix (0.5 ml, intramuscular, unknown application site at right side), contralaterally. Less than one week post vaccination with Infanrix hexa and Synflorix, on an unknown date between 11 November 2010 and 18 November 2010, the subject experienced bilateral leg swelling. Approximately one day post vaccination with Infanrix hexa and Synflorix, on 12 November 2010, the subject experienced swelling and erythema (no site specified). On an unknown day in November 2010 the subject was hospitalised for two days for this event. Sepsis was suspected (possible sepsis). The subject was treated with amoxicillin trihydrate + potassium clavulanate (Amoxiclav) for sepsis. On the next day, on an unknown day in November 2010, the subject was discharged from hospital. At the time of reporting, on 19 November 2010, the outcome of the events was unspecified. Follow-up information was received on 06 December 2010 from the reporting physician. After about six days, on 17 November 2010, all events were resolved. The vaccination courses with Infanrix hexa and Synflorix were discontinued. No further information will be available.

Company comment: Less than one week post vaccination with Infanrix hexa and Synflorix the 20 month-old subject experienced bilateral leg swelling and erythema. Sepsis was suspected but not confirmed. No etiological agent causing sepsis was reported. The subject recovered after hospitalization and antibiotherapy.

- **D0069690A (Germany): Injection site swelling, Injection site erythema, Sepsis**

This case was reported by a physician, via sales representative and described the occurrence of suspected sepsis in an 18-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. According to initial information, on 06 December 2010 the subject received the fourth dose of Infanrix hexa (left leg). Concurrently a dose of Synflorix was administered to the right leg. On an unspecified date within the following three days the subject developed swelling and redness at the injection site of Infanrix hexa. The reaction was the size of an adult's palm. Otherwise the subject was fit. There was no whining or fever. The subject was treated with cetirizine hydrochloride and cefaclor. At the time of reporting the outcome of the events was unspecified. Follow-up information was received on 29 December 2010 from the reporting physician by means of a completed questionnaire: Previous vaccinations with Infanrix hexa were well tolerated. On 06 December 2010 the

subject received the fourth dose of Infanrix hexa (intramuscular, left thigh). Concurrently a dose of Synflorix was administered contralesionally. The following day, on 07 December 2010, the subject developed swelling and redness at the injection site. The subject was treated with cetirizine hydrochloride and cefaclor (CEC) for suspected sepsis (not reported as an event, provided as indication of the treatment drug). On 10 December 2010 swelling and redness resolved. On an unspecified date in December 2010 the subject fully recovered.

Company comment: Site injection complication within 3 days post-vaccination with Infanrix hexa and Synflorix. complication. Sepsis was suspected but not confirmed and no etiological agent was reported. The event resolved after antibiotherapy.

- **D0072852A (Germany): Circulatory collapse, Sepsis, Shock, Crying, Pallor**

See Section 6.5.1 Cases with a fatal outcome.

6.5.2.7.12. Septic shock

One case of Septic shock was received during the period (D0069889A) and is described in Section 6.5.2.7.6 Meningitis pneumococcal.

6.5.2.8. Musculoskeletal and connective tissue disorders

6.5.2.8.1. Muscle spasms

Eight (8) cases of Muscle spasms were received during the period. In one case, muscle spasms were associated with an hypotonic-hyporesponsive episode and in another case with hypertonia. The muscle spasms were resolved in 2/8 cases. These cases are summarised in [Table 16](#).

Table 16 Summary of cases of Muscle spasms received during the period

6.5.2.8.2. Soft tissue necrosis

One (1) case of Soft tissue necrosis was reported during the period:

- **D0069239A (Germany): Soft tissue necrosis, Debridement, Incorrect route of drug administration**

This case was reported by a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2010030686) and described the occurrence of soft tissue necrosis in a 1-year-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. On an unspecified date in 2010, approximately six months prior to initial reporting, the subject received unspecified dose of Infanrix hexa (unknown route, right thigh). In 2010, approximately 6 months after vaccination with Infanrix hexa, the subject experienced sterile necrosis in subcutis of thigh (soft tissue necrosis). The subject was hospitalised on 19 July 2010 for 5 days for local excision of necrotic tissue. In 2010, the events were resolved. The paediatrician considered that the events were related to vaccination with Infanrix hexa. The paediatrician stated that this was the second subject with necrosis in his praxis and he had increased rates of swelling post vaccination since approximately two years. According to the surgery report, the subject had abscess forming fat tissue necrosis subcutaneous on right thigh after an older subcutaneous injection (intramuscular formulation administered by other route). This was surgically removed on 20 July 2010, without any complications. The wound was treated with gentamicin sulphate (Sulmycin). When the subject was discharged, the wound was not irritated. No further information will be available.

Company comment: Sterile soft tissue necrosis of the thigh in a 1-year-old male subject approximately 6 months after vaccination with Infanrix hexa. The complication recovered after adequate surgery. The surgery report states possible relation to incorrect route of drug administration (intramuscular formulation administered subcutaneously).

6.5.2.9. Nervous system disorders**6.5.2.9.1. Cerebral atrophy and Cerebral ischemia**

Three (3) cases of Cerebral atrophy/Cerebral ischemia were reported during the period:

- **B0686639A (Italy): Epilepsy, Cerebral ischaemia, Partial seizures**

This case was reported by a physician via a regulatory authority (IT-Agenzia Italiana del Farmaco # 128180) and described the occurrence of epileptic seizure in a 3-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Concurrent medications included Bisolvon. On 8 November 2010, the subject received unspecified dose of Infanrix hexa (intramuscular, injection site unknown). On 18 November 2010, 10 days after vaccination with Infanrix hexa, the subject experienced epileptic seizure. The subject was hospitalised where cardiac monitoring

was made. Relevant tests were performed: electroencephalogram showed epileptiform abnormalities in the right hemisphere and nuclear magnetic resonance with contrast liquid showed ischemic injury due to hypoxia in the right hemisphere. The subject was treated with anti-inflammatory (Anti inflammatory) and anticonvulsant (Anticonvulsants). At the time of reporting, the outcome of the event was unspecified. The regulatory authority reported that the event was possibly related to vaccination with Infanrix hexa. Follow-up information received on 2 December 2010: The vaccination performed on 8 November 2010, was 1st dose of Infanrix hexa. Nuclear magnetic resonance resulted as hypoxic ischemic lesion in the right hemisphere. At the time of follow-up, the subject was still under control, and other clinical exams were planned little time later. Follow-up information received on 6 June 2011: On 1st June, at the clinical control, are no longer present motor focal seizures. The subject made her anticonvulsant therapy.

Company comment: This 3-month-old female subject experienced partial seizures 10 days after 1st vaccination with Infanrix hexa. Complementary exams revealed a hypoxic ischemic lesion in the right hemisphere. The time sequence before partial seizures made the possible relationship to the product dubious.

- **B0716780A (Italy): Cardiac arrest, Multi-organ failure, Pneumonia aspiration, Cerebral ischaemia, Sudden infant death syndrome, Unresponsive to stimuli, Peripheral coldness, Staring, Musculoskeletal stiffness, Pyrexia, Somnolence.**

See Section 6.5.1 Cases with a Fatal Outcome.

- **D0070024A (Germany): Infantile spasms, Developmental delay, Posture abnormal, Restlessness, Crying, Hypotonia, Microcephaly, Cerebral atrophy, Bone marrow failure, Vomiting, Dehydration, Hypokalaemia, Pancytopenia.**

This case was reported by a public department for welfare and social affairs and described the occurrence of West's syndrome in a 4-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. On 8 May 2009 and 5 June 2009 the subject received 1st dose and 2nd dose of Infanrix hexa (unknown route and application site). The drug was reported as Infanrix, but the lot numbers clearly identified Infanrix hexa. At an unspecified time after vaccination with Infanrix hexa, the subject experienced convulsion disorder and developmental delay. It was unclear after which vaccination the events appeared. This case was assessed as medically serious by GSK. At the time of reporting the outcome of the events was unspecified. Co-suspect vaccination included pneumococcal vaccine (non-GSK) (Prevenar, Wyeth). On 5 June 2009 the subject received 2nd dose of Infanrix hexa (unknown route and application site), 2nd dose of Prevenar (unknown route and application site). On 09 June 2009 the subject suffered a bruise on forehead from a clay bowl falling down. Neurologic test was normal. On 17 July 2009 the subject received 3rd dose of Infanrix hexa (unknown route and application site), 3rd dose of Prevenar (unknown route and application site). Examination before vaccination was normal. The subject developed normally according to the parents. On 24 July 2009, 7 days after vaccination with Infanrix hexa and Prevenar, the parents reported about trunk bowing and feared about imperforate anus or faecal concretion. The subject was

hospitalised on 30 July 2009. The events were disabling. The subject was diagnosed with West's syndrome, severe developmental delay, axial hypotonia and microcephaly. During pregnancy the mother had vena-cava syndrome with a single syncope. The subject was the first and only child and was born spontaneously in 40 weeks of gestation with a weight of 3570 g, a size of 56 cm and an APGAR score of 9/10/10. The subject had a first convulsion on the day of second vaccination, on 05 June 2009 in the evening. On 30 July 2009 the subject was hospitalised with West's syndrome. Electroencephalogram (EEG) showed hypsarrhythmia. Magnetic resonance tomogram (MRT) in August 2009 was normal. The subject was treated with clonazepam, phenobarbitone (Phenobarbital), pyridoxine hydrochloride (Vitamin B6) and folic acid, but without effect. Under treatment with sulthiame (Sultiame) and levetiracetam the convulsions improved in frequency and severity. After treatment with tetracosactrin acetate (Synacthen) and prednisolone (Prednisolon) hypsarrhythmia ceased. The subject finally received levetiracetam and valproate. After discharge in August 2009 the subject was free from convulsions, but they recurred in September 2009. Vigabatrin was given. At the age of 7 months the subject's development was one month behind. From 30 November 2009 to 03 February 2010 the subject was treated in a specialised centre for epilepsy. In December 2009 and January 2010 the EEG results showed epileptic activity, especially posterior at both sides. Treatment with topiramate was started. Convulsions resolved under cyclic treatment with dexamethasone and omeprazole. In June 2010, at the age of 17 months, the subject had a developmental age of 7 months, with statomotor and psychomotor development delay. In August 2010 the subject was hospitalised with severe vomiting (not keeping any nutrition) and exsiccation. Laboratory tests showed hypokalemia and pancytopenia. All medication was stopped. Treatment with phenobarbitone (Luminal) and antibiotics was started. MRT showed dilated subarachnoid spaces in terms of cerebral atrophy. After bone marrow puncture in another hospital drug induced bone marrow depression was suspected. This resolved in further course and blood test normalised. The last examination report was from 30 November 2010, where the physician stated that EEG again showed increased generalised epileptic activity. No further information will be available.

Company comment: This 4-month-old female had a convulsion less than 1 day after 2nd dose of Infanrix hexa and Prevenar 55 days post-vaccination, she was diagnosed with West's syndrome severe developmental delay, axial hypotonia and microcephaly. The time sequence of signs apparition remained unclear but there is a medical anamnesis of neonatal convulsion unrelated to vaccination.

6.5.2.9.2. Seizures and Epilepsy

Seizures/Convulsions

During the period, 118 individual case reports were received including one of the following MedDRA preferred terms: **Clonic convulsion** (n=4), **Clonus** (n=8), **Convulsion** (53), **Febrile convulsion** (n=44¹), **Grand mal convulsion** (n=15),

¹ Including two cases received prior to this PSUR period but not included in a previous PSUR (B0674885A and B0631888A).

Myoclonus (n=10), **Partial seizures** (n=3), **Seizure like phenomena** (2), **Tonic clonic movements** (2) and **Tonic convulsion** (n=1). In some instances more than one MedDRA preferred term was included to describe the same event. These cases are summarised in [Table 17](#).

Table 17 Summary information for complete ‘Seizures/Convulsion’ data set (n=118)

Patient age (n=113)	Range	months	2-72
	Median	months	9.19

* Based on the presence of the following preferred terms in a seizure case:

- Febrile convulsion

OR

- Convulsion and Pyrexia in the same case.

Indeed some febrile seizures were described with the MedDRA PTs ‘Convulsion’ and ‘Pyrexia’ rather than with the PT ‘Febrile convulsion’.

Epilepsy

During the period, 19 individual case reports were received including at least one of the following MedDRA preferred terms: **Complex partial seizures** (1), **Epilepsy** (9), **Infantile spasms** (6), **Petit Mal Epilepsy** (3) and **Status epilepticus** (2). These cases are summarized in [Table 18](#), [Table 19](#), [Table 20](#) and [Table 21](#).

6.5.2.9.3. Demyelination and Demyelinating polyneuropathy

Two (2) cases of Demyelination/Demyelinating polyneuropathy were received during the period:

- **B0689246A (Saudia Arabia): Demyelination, Extrapyraxidal disorder, Neurological symptom, Irritability, Crying, Pyrexia, Strabismus.**

This case was reported by a physician via a sales representative and described the occurrence of demyelination in a 4-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevenar) for prophylaxis. On an unspecified date the subject received unspecified dose of Infanrix hexa (intramuscular, unknown injection site), unspecified dose of Prevenar (intramuscular, unknown injection site). Lot numbers not provided. The same day at night, less than one day after vaccination with Infanrix hexa and Prevenar, the subject experienced crying and fever. The 3rd day after vaccination, the baby showed irritability and acute neurological symptoms. The subject was hospitalised and the physician considered the events were disabling. An NMR was performed and showed pigmentations in the brain but no sign of infection. The subject was treated with azithromycin (Zitromax), dimethindene maleate (Fenistil) and antipyretic (Antipyretics). At the time of reporting, fever and crying were resolved but the other events were improved. The physician considered the events were possibly related to vaccination with Infanrix hexa and Prevenar. Follow up information received on 26 December 2010: Concurrent medications included Acyclovir (Zovirax) and Corticosteroid (Corticosteroids) for 3 weeks. In November 2010, the subject received 2nd dose of Infanrix hexa and 2nd dose of Prevenar. In November 2010, the subject experienced extra pyramidal symptoms, neurological symptom, irritability, crying, fever and eye squint. Relevant tests were performed (CT brain, CSF, CBC, EEG) but the results were not provided. An NMR was performed and showed patches of demyelination in the brain but no sign of infection. The final diagnosis was post vaccination acute demyelination. At the time of reporting, the events were improved. No additional information has been received. The case has been closed on 4 August 2011.

Company comment: This 4-month-old male subject experienced post vaccination acute demyelination (diagnosed at MRI) with acute neurological symptoms (extra pyramidal signs, irritability, crying, fever and eye squint) starting less than one day after 2nd dose of Infanrix hexa and Prevenar

- **D0069554A (Germany): Guillain-Barre syndrome, Congenital neuropathy, Demyelinating polyneuropathy, Hip deformity, Foot deformity, Motor developmental delay.**

See Section 6.5.2.9.6 Guillain-Barré syndrome.

6.5.2.9.4. Depressed level of consciousness

Twenty four (24) cases of Depressed level of consciousness were reported during the period and are summarised in [Table 22](#).

6.5.2.9.5. Encephalitis, Encephalopathy and Encephalic infection

Five (5) cases of Encephalitis/Encephalopathy/Encephalic infection were received during the period:

- **B0686208A (Italy): Encephalitis, Epilepsy.**

This case was reported by a physician via a sales representative and described the occurrence of possible encephalitis in a 3-month-old subject of unspecified gender who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Subject's medical history was negative. On 8 November 2010 the subject received 2nd dose of Infanrix hexa (unknown), lot number not provided. Less than one month after vaccination with Infanrix hexa, the subject experienced possible encephalitis and epileptic seizure. The subject was hospitalised. At the time of reporting the outcome of the events was unspecified.

Company comment: A 3-month-old subject experienced encephalopathy less than one month after 2nd dose of Infanrix hexa. Due to a lack of data, this case cannot be medically assessed.

- **D0070015A (Germany): Ataxia, Balance disorder, Encephalitis, Gait disturbance, Pyrexia, Upper respiratory tract infection, Otitis media acute, Cerebellar ataxia.**

This case was reported by a German regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2010038217) and described the occurrence of ataxia in a 16-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma). Past medical history was not provided. Previous vaccinations including three doses of combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and three doses of 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma), given on 28 September 2009, 04 January 2010 and 20 April 2010, were well tolerated. On 09 December 2010 the subject received the fourth dose of Infanrix hexa (0.5 ml, subcutaneous, right thigh) and the fourth dose of Prevenar 13 (0.5 ml, subcutaneous, left thigh), contralaterally. Approximately one day post vaccination with Infanrix hexa and Prevenar 13, on 10 December 2010, the subject experienced ataxia and tendency to fall towards the right side (balance disorder). The report suspected cerebellitis and/or encephalitis. The subject was hospitalised for an unknown period of time. In hospital cerebrospinal fluid (CSF) examination, electroencephalogram (EEG), cranial magnetic resonance tomogram (cMRT) and metabolic diagnoses were performed to confirm the events but the result of these examinations have not been provided. At the time of initial reporting, on 14 December 2010, the events were unresolved. The vaccination courses with Infanrix hexa and Prevenar 13 were discontinued. The vaccine was reported as diphtheria and tetanus toxoids and acellular pertussis vaccine (Infanrix,

GlaxoSmithKline), but according to lot number the subject was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline). Less than one day post vaccination with Infanrix hexa and Prevenar 13, on 09 December 2010, the subject experienced high fever of up to 39 degC. The following days the subject only showed subfebrile temperature of 37.5 degC. Approximately one day post vaccination with Infanrix hexa and Prevenar 13, on 10 December 2010, the subject experienced conspicuous staggering which improved over the next days. On 13 December 2010 the subject experienced conspicuous gait disturbance and was hospitalised for this event. Examinations, performed on 10 December 2010, showed upper respiratory tract infection. Cranial computed tomogram (CCT) was normal without pathogenic changes. Cerebrospinal fluid (CSF) showed increased CSF protein. CSF cell count could not be determined due to bloody and in parts coagulated CSF sample. Infection diagnostic of CSF were negative; CSF and blood cultures were sterile. Metabolic diagnostics were normal. Cranial magnetic resonance tomogram (cMRT) was normal. Electroencephalogram (EEG) showed beta superimposition due to medication and a conspicuous phase with a short group of irregular spike-slow-wave-complexes left frontocentral, control EEG was recommended. During course of hospitalisation the subject recovered and ataxia was clinically completely improved. During course of hospitalisation the subject showed high fever due to underlying respiratory tract infection. Regular laboratory examinations showed normal inflammatory parameters. Therefore the subject needed no treatment with antibiotics. The hospital physician(s) considered either post infectious cerebellar ataxia due to underlying respiratory tract infection, postvaccinal cerebellitis due to time context or otogenic ataxia associated with serous otitis media both sides (right more than left). On 18 December 2010 the subject was discharged from hospital in stable general condition against medical advice. No further information was available. At the time of follow-up reporting, on 21 December 2010, the events were resolved.

Company comment: This 16-month-old male subject experienced post infectious cerebellar ataxia due to underlying respiratory tract infection in the course of Infanrix hexa vaccination. A postvaccinal cerebellitis was compatible with the time sequence (one day post-vaccination with Infanrix hexa and Prevenar) but the ataxia was associated with serous otitis media both sides and finally recovered.

- **D0071549A (Germany): Encephalitis, Bronchitis, Lactic acidosis, Hyperglycaemia, Convulsion, Injection site induration, Pyrexia, Somnolence, Hypotonia, Depressed level of consciousness, Respiration abnormal, Cough, Pallor, Lip haematoma, General physical health deterioration,**

This case was reported by a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011015875) and described the occurrence of viral meningoencephalitis in a 4-month-old male subject who was vaccinated with 10 valent pneumococcal conjugate vaccine (Synflorix, GlaxoSmithKline), combined diphtheria, tetanus-acellular pertussis, hepatitis B and inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa) for prophylaxis. Former vaccinations included Synflorix on 04 March 2011 (same lot number), which was well tolerated. On 7 April 2011 the subject received 2nd dose of Synflorix (unknown route, right

thigh), 1st dose of Infanrix hexa (unknown route, left thigh). On 7 April 2011, less than one day after vaccination with Infanrix hexa and Synflorix, the subject experienced injection site induration. In the evening the subject had fever. This had resolved the next day and the subject was normal. On 10 April 2011 the subject developed somnolence. The subject was hospitalised for 25 days and the events were life threatening. The subject was diagnosed with viral meningoencephalitis. On 06 May 2011 the events were still unresolved. A hospital report was provided. According to this, the subject's medical history included respiratory syncytial virus pneumonia in January 2011. Since then there were recurrent respiratory infections. When the father wanted to give him the second baby bottle that morning, he found the subject with flaccid muscle tone and nonresponsive (could not be woken up), with rattling respiration. The subject had been lying at the side due to mild cough, but the face was not covered. When admitted, the subject was in reduced and instable general condition, with moaning, snapping breath, flaccid muscle tone, pale, non-responsive, without reaction to pain stimuli and had prolonged recapillarisation time. There was an extended hematoma at the lip at the right, but no other signs for injury. The subject had severe pulmonary obstruction (obstructive bronchitis diagnosed), lactic acidosis and hyperglycemia. First treatment included fluid substitution. Lactic acidosis quickly normalised. Blood glucose normalised on the second day and in further course all controls of lactate, blood glucose, blood gases and metabolic screening were normal. The subject was cardio-respiratory stable. Because of suspected encephalitis treatment with ampicillin trihydrate (Ampicillin), gentamicin sulphate (Gentamicin), cefotaxime (Cefotaxim) and acyclovir (Aciclovir) was started. Imaging diagnostics and electroencephalogram (EEG) confirmed the diagnosis of meningoencephalitis. As cerebrospinal fluid test showed 41 lymphocytic cells and respiratory infection, a viral genesis was suspected. After confirmation of negative bacteriological results, antibiotic treatment was stopped after three days. Aciclovir was continued for three weeks. On the second day the subject developed cerebral seizure and was treated with phenobarbitone (Phenobarbital). In further course there were no convulsions, but daily electroencephalogram (EEG) showed epileptic potentials and general changes in terms of retardation. Before discharge, EEG was still pathologic with missing sleeping structure and discrete multifocal irritability, but without seizure potentials. The subject was discharged with improved general condition, but still abnormal EEG and multiple neurologic abnormalities, including decreased spontaneous motor movement, frequent fisting, missing head control, missing active and targeted movements and no active sounding.

Company comment: This is a case of viral meningoencephalitis in a 4-month-old male subject. First symptoms occurred 3 days post vaccination with Infanrix hexa and Synflorix. The subject suffered from multiple neurologic sequelae. The hospital physician did not consider that the events were a reaction to vaccination.

- **B0692285A (France): Encephalitic infection, Convulsion, Dyskinesia, Fatigue, Pyrexia, Hypertonia, Depressed level of consciousness, Electroencephalogram abnormal**

This case was reported by the French regulatory authority (AF SSPS reference LL20100605) and described the occurrence of post infectious encephalitis in a 21-

month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (Prevenar, non-gsk) for prophylaxis. Medical condition was unspecified. On 08 December 2010, the subject received unspecified doses of Infanrix hexa (batch, route and injection site unknown) and of Prevenar (batch, route and injection site unknown). The subject experienced fever. On 09 December 2010, the subject was very tired and slept a lot. On 10 December 2010, the subject presented with convulsive status resistant to diazepam (Valium) and phenytoin (Dilantin) but effectively treated by midazolam hydrochloride (Hypnovel). Since that date, convulsion crisis recurred with abnormal movements, as pedaling, and hypertonia associated with a loss of contact (coded decreased level of consciousness). HSV1, HSV2, VZV, Epstein Barr virus and cytomegalovirus tests were negative. On 11 December 2010, an abnormal electroencephalogram was recorded with a very slow down line with a slight right hemispheric predominance without focusing suggestive of encephalitis. On 13 December 2010, HSV test was negative. Stool analysis revealed presence of campylobacter jejuni. Physicians concluded to post infectious encephalitis. The subject was hospitalised. At the time of reporting, the outcome of the events was unknown.

Company comment: Post-infectious encephalitis (campylobacter jejuni) in a 21-month-old female subject. Intermittent convulsive crises starting 2 days after vaccination with Infanrix hexa and Prevenar. According to AFSSaPS, the causal relationship between Infanrix hexa and Prevenar and the reported events is dubious.

- **D0071841A (Germany): Encephalopathy, Infantile spasms, Lennox-Gastaut syndrome, Dyskinesia, Developmental delay, Eye movement disorder, Motor dysfunction, Posture abnormal, Fatigue, Hyperhidrosis, Crying, Pallor, Diarrhoea, Musculoskeletal stiffness, Depressed level of consciousness.**

This case was reported by a physician and described the occurrence of epileptic encephalopathy in a 4-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. No epilepsy was known in the family. Co-suspect vaccination included pneumococcal vaccine (non-GSK) (Prevenar, Pfizer). On 9 February 2011 the subject received 1st dose of Infanrix hexa (unknown route and application site), 1st dose of Prevenar (unknown route and application site). In the end of February or beginning of March 2011, less than one month after vaccination with Infanrix hexa and Prevenar, the subject experienced decreased contact activity, eyes rolling, smacking and motor dysfunction. The subject was hospitalised and diagnosed with epileptic encephalopathy with regressive dyskinetic movement disorder and myocloni. Electroencephalogram (EEG) showed potentials typical for epilepsy. Magnetic resonance tomogram (MRT) of head was without pathologic findings. The family consulted another hospital, where the subject was diagnosed with West syndrome / Lennox Gastaut syndrome. The hospital report was not available to the reporting physician. There were no concurrent medical conditions or concurrent medications (Prevenar was not mentioned in the case follow-up). Infanrix hexa was given intramuscular, unknown gluteal. The subject developed convulsive disease /

West syndrome. The subject was hospitalised and the physician considered the events were disabling. The vaccination course with Infanrix hexa was discontinued. Follow-up information was received on 05 August 2011 via the German regulatory authority (PEI). The subject was born with umbilical cord around neck, but APGAR score was 10. In the evening after vaccination with Infanrix hexa and Prevenar, the subject could not keep the head straight (head posture abnormal) and had rolling eyes and restless head. The next day the subject developed sweating, tiredness and after three days high-pitched crying and regression of development (loss of known skills, speech and body control). In second week the subject was twitching and developed West syndrome. Medical stabilisation was difficult. At last (in July 2011), the subject was treated with sultiam (Ospolot). The subject had developed well until vaccination. Starting in the evening after vaccination and throughout the next three weeks, the subject developed problems holding the head with wagging the head, tiredness, pallor, diarrhea, sweating, stiff neck, was not responsive, stopped laughing, became more and more stiff, with high-pitched crying, twitching, headache and abdominal pain. The subject was hospitalised from 07 to 18 March 2011, 30 March to 09 April 2011, 16 to 18 May 2011 and 18 May to 10 June 2011. The hospital reports stated the following. The subject had two healthy siblings. After normal pregnancy, the subject was born spontaneously with a weight of 4040 g. Newborn screening and childhood examinations U1 to U3 were normal. On 31 December 2010 the subject had bronchitis, pharyngitis and purulent rhinitis. High amounts of *Klebsiella pneumoniae* were found in nose swab. U4 showed trunk hypotonia and physiotherapy was prescribed. On the same day vaccination was administered. After vaccination the subject's development was regressive, with less contact, tiredness, not responsive, rolling eyes, no sounding, loss of skills. When first hospitalised, the subject had hypotonia and movement disorder, but no infection, fever or diarrhea. Diagnoses included epileptic encephalopathy with developmental regression, West syndrome, dyskinetic movement disorder and muscular hypotonia. Electroencephalogram (EEG) was pathologic with hypersarrhythmia. Several convulsions were observed in hospital. Metabolic tests were normal, except for mildly increased methylmalonic acid in urine. Tests for amino acids in urine and plasma, acylcarnitin pattern in blood and lysosomal enzymes excluded GM1/2 gangliosidosis, CLN1/2 and Morbus Krabbe and showed no signs for metabolic diseases. Glutamin in plasma was mildly increased. Echocardiogram showed no cardiac hypertrophy. Treatment with vigabatrin (Sabril) was without effect and stopped by the parents without dose reduction. Treatment with pyridoxine hydrochloride (Vitamin B6) and calcium folinate (Folinic acid) was without effect. The parents started homeopathic treatment and quantum medicine with diverting harmful substances. During these measures harmful germs were reported, including *Lactobacillus acidophilus*, *lamblia*, fungi, *Pseudomonas aeruginosa* and multiple diseases, against which vaccination was possible, like *Haemophilus influenzae*. The parents refused medical treatment, because the disease had been caused by vaccination and anticonvulsive treatment had not been good for the child, causing constipation, which had to be removed with treatment for "gastritis" and "reflux" by a non-medical practitioner. The hospital physician strongly advised to start medical anticonvulsive treatment. After health care for the subject had been taken over by a youth welfare office and EEG was highly pathologic, treatment with steroids was started. This was followed by sulthiame (Ospolot). Timely relation to vaccination

was clear, but causal relation could not be assessed. Alternative causes were viral encephalitis (Cocksackie virus antibody found, which could also be maternal). A paediatrician was consulted for second assessment. The paediatrician had examined the subject on 31 December 2010 due to bacterial airways infection. At that time there were no neurologic symptoms. During examination on 22 March 2011, the subject was highly disabled, with disturbed perception, no reaction to stimuli, no contact to persons and extremely low muscle tone. The physician considered encephalitis most likely. Mercury intoxication, as suspected by the parents, was excluded.

Company comment: This 4-month-old female subject was diagnosed with West Syndrome/ Lennox-Gastaut syndrome less than one month after 1st dose of Infanrix hexa and Prevenar. Causal relationship to vaccination could not be formerly assessed and other etiologies were considered (metabolic, viral encephalitis).

6.5.2.9.6. Guillain-Barré syndrome

Two (2) cases of Guillain-Barré syndrome were received during the period:

- **B0691863A (Italy): Guillain-Barre syndrome, Neuropathy peripheral, Pyrexia, General physical health deterioration, Restlessness, Asthma, Decreased appetite, Gait disturbance, Dysstasia, Nuchal rigidity, Hyperaemia, Dysphonia, Hyporeflexia, Hypotonia, Asthenia**

This case was reported by a regulatory authority (IT-Agenzia Italiana del Farmaco # 130966) and described the occurrence of Guillain Barre syndrome in a 15-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevnar) for prophylaxis. On 8 September 2010 the subject received unspecified dose of Infanrix hexa (intramuscular, unknown, lot number not provided), unspecified dose of Prevnar (intramuscular, unknown). On 10 September 2010, 2 days after vaccination with Infanrix hexa and Prevnar, the subject experienced fever (NOS). On 22 September 2010, the patient experienced peripheral neuritis. On a date as yet unspecified, the patient experienced Guillain Barre syndrome. On 01 December 2010, he had recovered from the fever and peripheral neuritis and on a date as yet unspecified, he had recovered from Guillain Barre syndrome. The subject was hospitalised. Relevant test results included a CSF analysis and an NMR but no results were provided. The subject was treated with normal immunoglobulin (Immunoglobulin). The regulatory authority reported that the events were possibly related to vaccination with Infanrix hexa and Prevnar. Follow-up information received on 03 January 2011: The vaccine lot number for Infanrix Hexa was provided (A21FA780A). Follow-up information received on 19 April 2011: The child was hospitalized for the first time from 25 September 2010 till 30 September 2010 and from 08 October 2010 till 15 October 2010. Discharge letter: hospitalization from 25 September 2010 to 30 September 2010 Diagnosis: Guillain Barre Syndrome Medical history: patient was taken to emergency room. due to ingravescant fever since 10 September 2010 (vaccination date 08 September 2010). Since the start of fever the child presented with ingravescant general condition, with restlessness, asthenia,

decreased appetite. Since 22 September 2010 showed unsteady walk, with difficulty in maintaining erect position. On admission, the child was in a poor general condition and was unable to maintain standing position. He presented a pale-grayish complexion, decreased trophism, capillary refill inferior to 2 seconds. He presented also moderate skin hydration, hyperaemic pharynx and dysphonia as well as difficult breathing with chest wall retraction. Thorax examination showed reduced air intake, spare wheezes and rales. Clinical pattern suggestive of peripheral neuropathy with global asthenia. To be re-evaluated within 30 days. Course of hospitalization and prescribed therapy: during the first period of hospitalization the child showed clinical worsening with increased nuchal rigidity. For this reason, rachicentesis was performed. Then the child was treated with antibiotics. In the next days, marked improvement of general condition, associated with a still incomplete improvement of neurological condition, osteotendon reflexes, tone, walking and nuchal rigidity. The child was discharged in moderately good condition. Advice at discharge: antibiotic therapy: amoxi-clavulanic acid (Augmentin) 2ml 3xD until 04 October 2010 inclusive. Discharge letter: hospitalization from 08 October 2010 to 15 October 2010: Diagnosis: Guillain Barre Syndrome Medical history: patient already hospitalized for peripheral neuritis. At follow up visits the child's neurological condition had not improved. Therefore, a new hospitalization was decided in order to perform NMR of the brain and spinal cord under sedation, followed by therapy with immunoglobulins i.v. On admission: fair general condition, pale complexion, decreased trophism, capillary refill above 2 seconds, moderate skin hydration. Pink pharynx, normal breathing. Neurological visit: hypotonic child, shows difficulty in movement of upper limbs, no walking, no erect standing, no signs of meningeal irritation. Lab tests (08 October 2010): RBC 4.74 tera/L; HB 123 g/L; Ht 38%, MCV 79.2 fl/cell; PLT 476 giga/L; WBC 17.0 giga/L (neutrophils 9.9, leucocytes 5.6, monocytes 1.1 giga/L). CRP 0.7 mg/dL. Glycemia, albumin and ions normal. Lab tests (11 October 2010): RBC 9.90 tera/L; CRP < 0.5 mg/dL. Na 132 mEq/L. PT, aPTT normal. Brain/spinal chord NMR negative. Course of hospitalization and Prescribed therapy: on admission date, the child was drowsy and with leucocytosis, likely due to dehydration. He was treated with rehydrating solution; the next day therapy with immunoglobulins i.v. (400mg/Kg/die for 5 days) was started. Pre-treatment with Trimeton (chlorpheniramine). No adverse reactions observed. Neurological visit: upper limbs improvement observed. Further clinical improvement can be expected, which will be monitored closely through follow up visits.

Company comment: This case does not provide any supportive evidence for GBS diagnosis except for the clinical description. Results of diagnostic tests supportive of the diagnosis were not provided: CSF, EMG, NCS, and no investigation results of other possible etiology such as herpes infection. The febrile context 48 hours after vaccination could have triggered the occurrence of the neurologic syndrome that started 2 weeks after vaccination with Infanrix and Prevenar. Clinical neurological improvement after multiple hospitalization and therapy is reported. This case fulfils the Level 4 of diagnostic certainty of Brighton Collaboration GBS Working group criteria.

- **D0069554A (Germany): Guillain-Barre syndrome, Congenital neuropathy, Demyelinating polyneuropathy, Hip deformity, Foot deformity, Motor developmental delay**

This case was reported by a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2010034653) and described the occurrence of Guillain Barre syndrome in a 2-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Later vaccinations included pneumococcal vaccine (Prevenar, Wyeth) in December 2006, January 2007 and November 2007, combined measles, mumps and rubella vaccine, live, attenuated on 27 February 2008, meningococcal vaccine (NeisVac-C, Baxter Healthcare) on 24 February 2009, hepatitis A vaccine (Havrix pediatric, GSK) in July 2009. On 22 August 2006, 26 September 2006 and 24 October 2006 the subject received 1st dose, 2nd dose and 3rd dose of Infanrix hexa (unknown route, unknown thigh). At an unspecified time after vaccination with Infanrix hexa, the subject experienced Guillain Barre syndrome (GBS). The subject developed GBS during infancy, but it was not clarified after which vaccination. The subject was hospitalised. At the time of reporting the event was unresolved. Follow-up information was received on 19 January 2011 via the German regulatory authority (PEI). Later vaccinations also included another dose of Infanrix hexa on 01 August 2007, combined measles, mumps and rubella vaccine, live, attenuated (Priorix, GSK) in June 2007 and varicella vaccine (Varivax) in June 2007. Ambulatory orthopaedic examination was performed on 23 October 2007. During early childhood the subject showed statomotor developmental delay and was diagnosed with hydrocephalus internus. The subject had first problems, later diagnosed as coxa valga and antetortia at both sides and pes valgus. The subject received regular physiotherapy. From 09 March to 20 April 2010 the subject was hospitalised for rehabilitation measures. The following was reported for anamnesis: The subject was born in 40+5 weeks of gestation by emergency caesarean section, after complications because of unusual position. At birth the subject had a weight of 3540 g, a size of 50 cm and an Apgar score of 10/10. The subject was breast-fed for eight months and received vitamin D and fluor prophylaxis for 20 months. The subject was seldom ill, but had three-day fever once. There were no allergies. The subject had congenital hydrocephalus internus and mild Dandy-Walter disease variant, but no other malformations. The subject still received regular physiotherapy and had Swash-Orthesis at night until January 2010. During hospitalisation from 04 to 07 August 2010 a muscle conduction velocity (MLG) examination showed signs for severe polytopic demyelinating neuropathy. In a medical report from 21 October 2010 the diagnosis was polyneuropathy, differential diagnosis congenital hypomyelinating neuropathy. No further information will be available.

Company comment: This case fulfils the Level 4 of diagnostic certainty of Brighton Collaboration GBS Working group criteria. The physician did not consider GBS as primary possible diagnosis and stated a chronic inflammatory demyelinating polyneuropathy (CIDP) has to be considered more likely, although the course of disease was unusual. Other differential diagnoses have been postulated (congenital hypomyelinating neuropathy).

6.5.2.9.7. Hemiparesis

One (1) case of Hemiparesis was received during the period (D0071075A) and is described in Section [6.5.2.9.12](#) Thalamus haemorrhage.

6.5.2.9.8. Lennox-Gastaut syndrome

One (1) case of Lennox-Gastaut syndrome was received during the period (D0071841A) and is described in Section [6.5.2.9.5](#) Encephalitis, Encephalopathy and Encephalic infection.

6.5.2.9.9. Loss of consciousness

Thirty five (35) cases of Loss of consciousness were reported during the period and are summarized in [Table 23](#). This table also includes one case received prior to the period of this report but never included in a previous PSUR (B0591710A). This case's ID is marked by a '*' in [Table 23](#).

Table 23 Summary of cases of Loss of consciousness received during the period

6.5.2.9.12. Thalamus haemorrhage

One (1) case of Thalamus haemorrhage was received during the period:

- **D0071075A (Germany): Thalamus haemorrhage, Convulsion, Facial paresis, Hemiparesis, Hypophagia, Restlessness, Pyrexia, Screaming, Somnolence, Pallor, Hyperaesthesia, Eyelid oedema, Abdominal distension, Hypotonia, Apnoea, Gaze palsy.**

This case was reported by a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011011270) and described the occurrence of thalamic bleeding in a 3-month-old male subject who was vaccinated with live attenuated human rotavirus vaccine (Rotarix, GlaxoSmithKline), combined diphtheria, tetanus-acellular pertussis, hepatitis B and inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa) for prophylaxis. On 24 March 2011 the subject received 1st dose of Rotarix (liquid, oral), 1st dose of Infanrix hexa (intramuscular, unknown injection site). On 29 March 2011, 5 days after vaccination with Infanrix hexa and Rotarix, the subject experienced thalamic bleeding of capsula interna at the right side. The subject was hospitalised. A hospital report was received on 01 June 2011 via the German regulatory authority (PEI). The subject was hospitalised from 29 March to 11 April 2011, and then transferred to another unit. Pregnancy, birth and further development of the infant had been normal. On 24 March 2011 the subject received Rotarix and Infanrix hexa. On 25 March 2011 the subject had fever up to 37.7 degC, but else no symptoms. In the night from 28 to 29 March 2011 the subject developed restlessness, screaming, reduced food intake and was hard to wake up. A paediatrician was consulted and the subject was admitted to hospital with the suspect of acute abdomen. In hospital acute abdomen was excluded. Sonogram showed recent thalamic bleeding at the right and the subject was transferred to the reporting hospital for further diagnostics. When transferred, the subject was pale with marble skin, sensitive to touch, but without hematoma or petechiae. The subject had lid edema and abdominal distension, but normal bowel sounds. There were neurological deficits. Cranial magnetic resonance tomogram (MRT) confirmed right-sided bleeding in thalamic centre region and capsula interna. A malformation of vessels was excluded. Extended hematologic diagnostics excluded factor deficiency and thrombophilia and the genesis of bleeding kept unclear. There was no sign for viral infection. Only rotavirus antigen was found in stool, which was caused by rotavirus vaccination. In further course, electroencephalogram (EEG) showed regional function disorder and increased predisposition for convulsions and the subject was treated with phenobarbitone (Phenobarbital). EEG on 06 April 2011 showed mild improvement. Initial neurologic symptoms included decreased muscle tone at the left with increased tendency for stretching of extremities at the left. The subject also had gaze palsy to the right. Additional diagnoses in hospital included cerebral convulsion, peripheral facial paresis and left-sided hemiparesis. The subject was treated with dextrose (Glucose), electrolytes, phytomenadione (Konakion), midazolam hydrochloride (Dormicum), paracetamol, chloral hydrate, and ergocalciferol (Vigantoletten). Intensive physiotherapy was started for compensation of neurologic deficits. Outstanding vaccination with Pneumococcal vaccine (unknown manufacturer) was performed stationary on 09 April 2011. After this, the subject developed solitary episodes of apnea, but without affection of other vital

parameters. The physician stated that there will probably be mental or motor sequelae. The hospital physician did not consider a causal relation of thalamic bleeding to vaccination. No further information will be available.

Company comment: This 3-month year old male subject experienced a thalamic bleeding of the right capsula interna with multiple neurological complications 5 days after 1st vaccination with Infanrix hexa and Rotarix. The treating physician did not suspect a causal relationship.

6.5.2.9.13. VIth nerve paralysis

One (1) case of VIth nerve paralysis was received during the period:

- **B0681066A (Belgium): VIth nerve paralysis, Strabismus.**

This case was reported by a healthcare professional and described the occurrence of sixth nerve paralysis in a 15-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) and meningococcal polysaccharide vaccine group c (non-gsk) (Menjugate) for prophylaxis. Previous and/or concurrent vaccination included dtpa-polio-hib (non-gsk) ;Sanofi Pasteur MSD;unknown;unknown given on an unspecified date. On 13 September 2010, the subject received 1st dose of Infanrix hexa (administration site and route unknown) and an unspecified dose of Menjugate (unknown). The subject had previously received 3 doses of Pentavac during his first year. The 4th dose was administered with Infanrix hexa (which contained vaccine against hepatitis B virus). On 5 October 2010, 22 days after vaccination with Infanrix hexa and Menjugate, the subject experienced paralysis of cranial nerve VI external oculomotor on left eye. No fever was experienced. On 6 and 8 October 2010, the subject was seen by the ophthalmologist who decided to transfer him to the emergency department. The subject was hospitalised till 12 October 2010. On 11 October 2010, several tests were performed under general anesthesia. All the tests were negative: cerebral magnetic resonance imaging, blood test, lumbar puncture and ocular fundus. No treatment was administered. According to the neurologist, the event was not due to a problem of the brain but possibly due to Infanrix hexa and Menjugate and asked to stop vaccination against hepatitis B virus. At the time of reporting, the event was unresolved. There was a paralysis of the left cranial nerve VI considered as a post viral paralysis or post vaccinal. During the hospitalisation, left paralysis of cranial nerve VI persisted without deterioration and without improvement. The subject didn't show other sign of neurological lesions. He remained with excellent general status, the appetite was excellent. The investigation performed by him didn't show for the moment any cause for the paralysis. He should be followed by his ophthalmologist in order to determine whether any treatment was requested. Some oligoclonal bands were noted in the cerebrospinal fluid with uncertain significance. It was advised to the parents to discontinue temporary the vaccination and to reevaluate this condition in the future.

Company comment: Post-infectious or post-vaccinal paralysis of cranial nerve VI in a 15-month-old male subject 22 days after vaccination with Infanrix hexa and Menjugate. Time to onset seems long for causality.

6.5.2.9.14. VIIth nerve paralysis

Two (2) cases of VIIth nerve paralysis were received during the period:

- **B0728966A (France): VIIth nerve paralysis, Pain in extremity, Mobility decreased, Oedema peripheral, Erythema, Pyrexia, Facial asymmetry.**

This case was reported by a pediatrician, via a GSK sales representative, and described the occurrence of paralysis of mouth in a 23-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Subject's father experienced rythm disorder after Influenza vaccination (nos) please see linked case B0728963A (same family, same reporter). In 2011, the subject received an unspecified dose of Infanrix hexa (batch, route and injection site unknown). About 48 hours after vaccination with Infanrix hexa, the subject experienced paralysis of mouth, limb pain with limb decreased mobility. This case was assessed as medically serious by GSK. At the time of reporting, the outcomes of the events were unspecified. Previous vaccination included one dose of Priorix given on 22 November 2010 and one dose of Prevenar given on 13 September 2010. The subject had a febril reaction after this vaccination with Prevenar. On 19 May 2011, the subject received a fourth dose of Infanrix hexa in thigh probably in the left side. On 20 May 2011, the subject had fever at 39 degrees Celsius wich within 24 hours and elusive lower limbs edema and redness (red plaques). On 21 May 2011, 48 hours after vaccination, the subject developped intermittent and flabby right facial asymmetry at mouth level. Several hospital consultations at pediatric unit were made (without hospitalization). Asymmetry persisted but improved and occurred mainly when the subject was tired. It was more visible when he smiled. On 23 June 2011 at consultation, asymmetry persisted. Neurological investigations were planned. On 04 July 2011, the subject was hospitalized for bilateral eyelid edema, not related to vaccination according to the physician. The reporter's assessment was not provided.

Company comment: This 23-month-old male subject experienced intermittent facial paresis starting 48 hours after combined vaccination with Infanrix hexa and Prevenar. A febrile reaction to Prevenar occurred 24 hours prior to the symptoms.

- **D0071922A (Germany): VIIth nerve paralysis, Facial paresis**

This case was reported by a physician via a sales representative and described the occurrence of central facial paresis left in a 4-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma). Less than one day post vaccination with the third doses of Infanrix hexa and Prevenar 13, on 22 March 2011, the subject experienced the first episode of asymmetrical crying face (asymmetrical status facial side drooping). Approximately 49 days with the third doses of Infanrix hexa and Prevenar 13, on 10 May 2011, the subject experienced another episode of asymmetrical crying face (asymmetrical status facial side drooping). Approximately 69 days with the third doses of Infanrix hexa and Prevenar

13, on 30 May 2011, the subject experienced a very severe episode of asymmetrical crying face (asymmetrical status facial side drooping) and was hospitalised for an unknown period of time. In hospital the subject was diagnosed with central facial paresis left of unknown origin by a neuropaediatrician. Ultrasound and cranial computed tomogram (CCT) as well as motor function tests were normal. The reporting physician considered that the event may cause permanent damage. The reporting physician considered that the event was possibly related to vaccination with Infanrix hexa. Family anamnesis included Weber's disease (Sturge-Weber syndrome) of the mother which had already caused amputation of one leg, abnormal nodules of the 8-year-old sister which needed surgical treatment, and lipomyelomeningocele of the twin sister which needed surgical treatment followed by physiotherapy. Since the subject was two months old the subject showed reduced movement of the left side of the face when crying. The subject was diagnosed with facial paresis left. By anamnesis and differential diagnosis no involvement of the cranial branch was observed. No cause of the event could be determined. Birth anamnesis was normal. Mental and motor development was normal. The hospital physicians considered that the event was at the moment no serious neurological disease and recommended monitoring of the event. No further information will be available.

Company comment: This 4-month-old male subject experienced 2 episodes of transient facial nerve palsy less than one day and 69 days after vaccination with 3rd dose of Infanrix hexa. There was no compelling evidence that the event was causally related to the combined vaccination with Infanrix hexa and Prevenar.

6.5.2.10. Respiratory, thoracic and mediastinal disorders

6.5.2.10.1. Apparent life threatening event

Four (4) cases of Apparent life threatening event were received during the period:

- **B0691130A (France): Apnoea, Bradycardia, Oxygen saturation decreased, Blood pressure decreased, Apparent life threatening event, Urine output decreased, Cholinergic syndrome, Eye movement disorder, Gastroesophageal reflux disease, Aspiration**

This case was reported by the French regulatory authority (AFSSaPS reference ST20100963) and described the occurrence of apnea in a 1-month and 29 day-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and pneumococcal vaccine (Prevenar, non-gsk) for prophylaxis. Concurrent medical conditions included prematurity (born at 27 weeks of amenorrhea). The subject weighed 2.25 kg. On 15 December 2010, at about 11:00 the subject received a 1st dose of Infanrix hexa (intramuscular, batch and injection site unknown) and a 1st dose of Prevenar (intramuscular, batch and injection site unknown). On 15 December 2010 at about 16:00, approximately five hours after vaccination with Infanrix hexa and Prevenar, the subject presented with several episodes of apnea with bradycardia and oxygen desaturation which required a mechanical ventilation (Continuous positive airway pressure) and at 19:00 intubation as apnea, bradycardia and desaturation persisted. On 16 December 2010, the subject

remained dependent on mechanical ventilation. Blood pressure and diuresis decreased. The subject was treated with dopamine at 7.5 g/kg/min. At 17:00, blood pressure and diuresis normalized. The subject remained intubated. The AFSSAPS also coded a near sudden infant death syndrome. The subject was hospitalised and the regulatory authority reported that the events were life threatening. At the time of reporting, the events were unresolved. According to the French method of assessment, the AFSSaPS considered the causal relationship between Infanrix hexa and Prevenar and the reported events as dubious. Upon follow-up received on 11 January 2011: Birth weight of the subject was 1192 g. Medical condition included neonatal apnea treated with caffeine until 30 November 2010 and with doxapram chlorhydrate (Dopram). On 15 December 2010, a possible pulmonary inhalation was considered, as the subject might had reflux. Clinical course was favourable. At the time of reporting, the events were resolved. Upon follow-up received on 17 January 2011: Contacted by phone, the intensive care pediatrician reported a severe vagal hypertonía demonstrated by oculomotor reflexes disturbance. At an unknown date, the subject had bilateral inguinal hernia surgery. At this time, he was treated with atropine.

Company comment: Case of near sudden infant death syndrome in a prematurely born 2- month-old male subject 5 hours after first vaccination with Infanrix hexa and Prevenar. The subject was hospitalized and recovered completely. According to the French method of assessment, the AFSSaPS considered the causal relationship between Infanrix hexa and Prevenar and the reported events as dubious.

- **B0707044A (Netherlands): Anaemia, Milk allergy, Gastroesophageal reflux disease, Body temperature increased, Gastrointestinal motility disorder**

This case was reported by a regulatory authority (NL-College ter Beoordeling van Geneesmiddelen # NL-LRB-118313) and described the occurrence of apparent life threatening event in a 2-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and pneumococcal vaccines (non-GSK) (Prevenar) for prophylaxis. Concurrent medical conditions included anemia (depth and underlying cause unspecified), recurrent elevated body temperature, defecation disorder (undulating defecation frequency), suspected cow's milk allergy and suspected gastroesophageal reflux. Concurrent medications included Ranitidine hydrochloride (Zantac), Domperidone (Motilium) and Macrogol 4000 (Forlax). On 28 February 2011 the subject received 1st dose of Infanrix hexa (intramuscular, unknown injection site), 1st dose of Prevenar (intramuscular, unknown injection site). Lot numbers were not provided. On 1 March 2011, 8 hours after vaccination with Infanrix hexa and Prevenar, the subject experienced apparent life threatening event. The subject was hospitalised. At the time of reporting the event was improved. The regulatory authority reported that the event was possibly related to vaccination with Infanrix hexa and Prevenar. No further information is expected, the regulatory Authority has provided GSK with all the available information for the time being, if they ever get any further information they will send it to GSK. Therefore the case has been closed.

Company comment: Apparent life threatening event in a 2-month-old male subject 8 hours after combined 1st vaccination with Infanrix hexa and Prevenar. There is insufficient information to assess this case.

- **D0071146A (Germany) Apparent life threatening event, Pallor, Loss of consciousness, Erythema, Respiratory arrest, Somnolence**

This case was reported by a physician, via Pfizer Pharma GmbH, and described the occurrence of near miss sudden infant death syndrome in a 12-week-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and live attenuated human rotavirus vaccine (Rotarix, GlaxoSmithKline) for prophylaxis. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma). There was no relevant medical history. On 13 April 2011 the subject received the first dose of Infanrix hexa (0.5 ml, intramuscular, right thigh), the first dose of Prevenar 13 (0.5 ml, intramuscular, left thigh), contralaterally, and the first dose of Rotarix (0.5 ml, unknown formulation, oral). Post vaccination the subject was sleepy. Approximately two and a half hours post vaccination with Infanrix hexa, Prevenar 13 and Rotarix, on 13 April 2011, the subject experienced near miss sudden infant death syndrome with pallor, loss of consciousness, skin red and stopped breathing. The physician considered the events were life threatening. After measures by the grandmother with lifting up and shaking, the subject regained consciousness and the conditions normalised. Since 15 April 2011 the subject was monitored for breathing and heart sounds. Additionally the subject received supply with "vital fire". At the time of reporting, on 19 April 2011, a events were resolved. The physician considered the events were possibly related to vaccination with Infanrix hexa, Prevenar 13 and Rotarix. Follow-up information was received on 05 May 2011 via Pfizer. Vaccination was on 13 April 2011 at 13:00. The physician considered that the events were clinically significant (or requiring intervention). Follow-up information was received on 31 October 2011 via case D0073203A received from a German regulatory authority (DE-Paul-Ehrlich-Institut). Approximately five hours post vaccination with the second dose of Rotarix, given on 26 May 2011, the subject experienced similar events (severe pallor, decreased heart and respiratory function) which have repeatedly triggered monitor alarm. For additional information please see case D0073203A. No further information will be available.

Company comment: Case of near sudden death infant syndrome in a 3-month-old female subject 2 hours after first dose of Infanrix hexa, Prevenar and Rotarix. The event resolved spontaneously. A similar event was reported 5 hours after the second dose of Rotarix.

- **D0071421A (Germany) Apparent life threatening event, Altered state of consciousness, Hypothyroidism, Neutropenia, Staring, Hypotonia, Pallor, Respiratory arrest, Crying**

This case was reported by a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011015251) and described the occurrence of apparent life threatening event in a 4-month-old male subject who was vaccinated with synflorix (GlaxoSmithKline) for prophylaxis. Co-suspect vaccination included combined diphtheria, tetanus-

acellular pertussis, hepatitis B and inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa). Past medical history was not provided. Concurrent medications included D-fluorethen. On 29 March 2011 the subject received 1st dose of Synflorix (intramuscular, unknown gluteal) and 1st dose of Infanrix hexa (intramuscular, unknown gluteal). On 2 April 2011 in the evening, 4 days after vaccination with Infanrix hexa and Synflorix, the subject was suddenly staring, eyes did not roll back. Muscle tone was flaccid and complexion pale. The subject's mother explained it "like dead" (consciousness disturbed). After stimulation the subject started breathing again and crying. The subject was admitted to hospital and hospitalized for 5 days. At admission to hospital the subject was in stable general condition, awake and conscious. Therapy and course The subject was admitted to hospital because of possible apparent life threatening event lasting for seconds. Monitoring was inconspicuously during stationary stay. No repeated similar event appeared. The examinations performed including metabolism diagnostics showed no pathological finding. Metabolism disturbance and central regulatory disturbance could be excluded. The subject showed latent hypothyroidism (inconspicuously peripheral thyroid parameters) and temporary neutropenia. The subject was treated with potassium iodide (Jodid). On 06 April 2011 the subject was discharged from hospital in good general condition. No further information will be available.

Company comment: Case of possible apparent life threatening event lasting for a few seconds in a 4-month-old male subject 4 days after combined vaccination with Infanrix hexa and Synflorix. Extensive examinations found no pathology. The event resolved spontaneously.

6.5.2.10.2. Asphyxia

One (1) case of Asphyxia was reported during the period (B0705290A) and is described in Section 6.5.1 Cases with a fatal outcome.

6.5.2.10.3. Respiratory arrest

Seven (7) cases of Respiratory arrest were received during the period:

- **B0706503A (Thailand): Shock, Respiratory arrest, Cardiac arrest, Pyrexia, Somnolence, Hypotonia, Vomiting, Crying, Apnoea.**

See Section 6.5.1 Cases with a Fatal Outcome.

- **B0710929A (Netherlands): Hypotonic-hyporesponsive episode, Respiratory arrest, Crying**

This case was reported by a regulatory authority (NL-College ter Beoordeling van Geneesmiddelen # NL-LRB-118929) and described the occurrence of hypotonic-hyporesponsive episode in a 2-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) and pneumococcal vaccines (non-gsk) (Prevenar) for prophylaxis. She was born at 35.4 weeks, she grew slowly and will be examined for achalasia. On 11 March 2011, the subject received 1st dose of Infanrix hexa (intramuscular,

administration site unknown, batch number not provided) and 1st dose of Prevenar (intramuscular, unknown). On 11 March 2011, within minutes of vaccination with Infanrix hexa and Prevenar, the subject experienced hypotonic-hyporesponsive episode. She stopped crying and seemed to fall asleep, she was white and stopped breathing. After touching her cheek, she started to cry and regained colour, but then the same happened again. These episodes repeated themselves 5 times. The subject was hospitalised for one day. In the hospital, she was well again. At the time of reporting, the events were resolved. The regulatory authority reported that the events were probably related to vaccination with Infanrix hexa and Prevenar. No further information is expected, the regulatory Authority has provided GSK with all the available information for the time being, if they ever get any further information they will send it to GSK.

Company comment: Case suggestive of breath holding spells in a 2-month-old female subject minutes after vaccination with first dose of Infanrix hexa and Prevenar. The event resolved spontaneously. The subject was hospitalized for 1 day but no information on examinations was included.

- **B0741007A (Netherlands): Respiratory arrest, Depressed level of consciousness, Breath holding, Crying, Eye movement disorder, Skin discolouration, Pallor**

This case was reported by a regulatory authority (NL-College ter Beoordeling van Geneesmiddelen # NL-LRB-126405) and described the occurrence of stopped breathing in a 10-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) for prophylaxis. The subject's medical history included planned cesarean section birth with weight of 5000g. On 9 August 2011, the subject received 4th dose of Infanrix hexa (.5 ml, intramuscular, injection site unknown, batch number not provided). On 9 August 2011, immediately after vaccination with Infanrix hexa, the subject was crying for 1 minute. After 1 minute of crying, she stopped breathing and her eyes turned backwards. She did not react for 10 seconds, her face was purple, but turned white shortly after this. When she was taken on the arm, she started breathing again and cried. She was very pale and grew less pale after she was lied down. After half an hour, she went homewards, still somewhat pale. This case was assessed as medically serious by GSK. At the time of reporting, the breath holding spells, stopped breathing and not responsiveness were resolved and the outcome of other events was unspecified. Face turned white was unresolved. The regulatory authority reported that the breath holding spells was probably related to vaccination with Infanrix hexa. No further information is expected, the regulatory Authority has provided GSK with all the available information for the time being, if they ever get any further information they will send it to GSK.

Company comment: Case suggestive of breath holding spells in a 10-month-old female subject minutes after vaccination with 4th dose of Infanrix hexa. The event resolved spontaneously.

- **D0069889A (Germany): Meningitis pneumococcal, Grand mal convulsion, Epilepsy, Hydrocephalus, Subdural hygroma, Subdural empyema, Anaemia, Generalised oedema, Ileus paralytic, Conjunctivitis, Septic shock, Pneumonia**

primary atypical, Neurosurgery, Pyrexia, Abdominal distension, Ill-defined disorder, Restlessness, Hyperaesthesia, Oligodipsia, Eye movement disorder, Hypertonia, Tachycardia, Oxygen saturation decreased, Ascites, Respiratory arrest, Drug ineffective, Cyanosis, Splenomegaly

See Section 6.5.2.7.6 Meningitis pneumococcal.

- **D0070901A (Germany):Circulatory collapse, Respiratory arrest, Cyanosis, Hypotonic-hyporesponsive episode, Screaming, Agitation, Hypotonia, Peripheral coldness, Ill-defined disorder, Fatigue, Pyrexia**

This case was reported by a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011009758) and described the occurrence of circulatory collapse in a 12-week-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline for prophylaxis. Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer). Previous vaccinations were well tolerated. On 22 March 2011 the subject received 1st dose of Infanrix hexa (unknown route, left thigh), together with 1st dose of Prevenar 13 (unknown route, right thigh). On the same day, the subject experienced hypotonic-hyporesponsive episode with circulatory collapse. The event was resolved after 1 minute. The subject was hospitalised for observation. Electroencephalogram showed normal findings. A seizure was excluded. The reporting Health Professional was uncertain whether the event was life threatening. Follow-up was received from the regulatory authority on 25 August 2011, including a hospital report. The subject was hospitalised for 2 days from 22 to 23 March 2011. Possible affect spasm was diagnosed. On 22 March 2011, the subject experienced screaming and inability to calm down. On the arm of the mother, the subject suddenly experienced atonia and stopped breathing. The skin of the face was cyanotic (cyanosis). There was no clonus. The subject had cold skin. After 1-2 minutes, the events were resolved. Afterwards, the subject opened his eyes and was whining and tired. There was no vomiting. Body temperature was 37.6 degC (fever). There was no family history of chronic diseases or convulsive disorder. On admission examination, neurological examinations showed normal findings. During monitoring in the hospital there were no unusual neurological findings and no further spasm. On discharge from hospital the subject was in good general condition. Follow-up was received from the regulatory authority on 26 August 2011, including a questionnaire. There was no concurrent medical condition. There were no anamnestic characteristics. On 22 March 2011 the subject received 1st dose of Infanrix hexa (intramuscular, left thigh), together with 1st dose of Prevenar 13 (intramuscular, right thigh). On 22 March 2011, 7 hours after vaccination with Infanrix hexa and Prevenar 13, the subject experienced circulatory collapse and hypotonic-hyporesponsive episode. The event was resolved after stimulation, after approximately 1 minute. The subject was hospitalised. Blood-taking and electroencephalogram were performed and showed normal findings. The reporting physician considered that the events were related to vaccination with Infanrix hexa and Prevenar 13. The vaccination course with Infanrix hexa was discontinued. No further information will be available.

Company comment: Case suggestive of breath holding spells in a 12-week-old male subject 7 hours after vaccination with 1st dose of Infanrix hexa and Prevenar. The event resolved after stimulation. The subject was hospitalized and no pathology was found.

- **D0071146A (Germany) Apparent life threatening event, Pallor, Loss of consciousness, Erythema, Respiratory arrest, Somnolence**
See Section 6.5.2.10.1 Apparent life threatening event.
- **D0071421A (Germany) Apparent life threatening event, Altered state of consciousness, Hypothyroidism, Neutropenia, Staring, Hypotonia, Pallor, Respiratory arrest, Crying**
See Section 6.5.2.10.1 Apparent life threatening event.

6.5.2.11. Skin and subcutaneous tissue disorders

6.5.2.11.1. Angioedema

Four (4) cases of angioderma were reported over the period. These cases are described below.

- **B0691862A (Italy): Angioedema**
This case was reported by a regulatory authority (IT-Agenzia Italiana del Farmaco # 130512) and described the occurrence of angioedema (face) in a 5-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevnar 13) for prophylaxis. On 17 December 2010 the subject received unspecified dose of Infanrix hexa (.5 ml, intramuscular, unknown), unspecified dose of Prevnar 13 (.5 ml, intramuscular, unknown). On 17 December 2010, less than one day after vaccination with Infanrix hexa and Prevnar 13, the subject experienced angioedema (face). This case was assessed as medically serious by GSK. Relevant test results included C-reactive protein (1.18 mg/dl), LDH (261 IU/L) and WBC (9590/mm³). On 18 December 2010, the event was resolved. The regulatory authority reported that the event was possibly related to vaccination with Infanrix hexa and Prevnar. No additional information could be obtained and this case has been closed.

Company comment: Angioedema of the face in a 5-month-old female subject less than 1 day after combined vaccination with Infanrix hexa and Prevenar. The event resolved spontaneously within 1 day.

- **B0730009A (Italy): Angioedema, Urticaria**
This case was reported by a regulatory authority (IT-Agenzia Italiana del Farmaco # 143398) and described the occurrence of angioedema in a 13-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) for prophylaxis. On 4 May 2011, the subject

received 1st dose of Infanrix hexa (intramuscular, administration site unknown). On 4 May 2011, less than one day after vaccination with Infanrix hexa, the subject experienced angioedema and urticaria of right thigh. This case was assessed as medically serious by GSK. The subject was treated with ice. At the time of reporting, the outcome of the events was unspecified.

Company comment: This case lacks data on the subject's medical history and other possible diagnosis.

- **B0741876A (Italy): Angioedema**

This case was reported by a regulatory authority (IT-Agenzia Italiana del Farmaco # 146655) and described the occurrence of giant urticaria in a 11-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Concurrent vaccination included pneumococcal vaccines (non-gsk) given on 17 August 2011. On 17 August 2011, the subject received unspecified dose of Infanrix hexa (unknown route of administration, unknown site of injection). On 17 August 2011, less than one day after vaccination with Infanrix hexa, the subject experienced giant urticaria. This case was assessed as medically serious by GSK. The subject was treated with betamethasone (Bentelan) and oxatomide (Tinset). At the time of reporting, the event was improved

Company comment: This case lacks data on the subject's medical history and other possible diagnosis.

- **B0749275A (Italy): Angioedema, Hyperaemia, Pyrexia**

This case was reported by a regulatory authority (IT-Agenzia Italiana del Farmaco # 147929) and described the occurrence of giant urticaria in a 5-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) and pneumococcal vaccines (non-gsk) (Prevenar 13) for prophylaxis. Concurrent vaccination included combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. ;GlaxoSmithKline;unknown;unknown given on 20 June 2011. No adverse events occurred. On 18 August 2011, the subject received 2nd dose of Infanrix hexa (administration site and route unknown) and an unspecified dose of Prevenar 13 (unknown). On 18 August 2011, less than one day after vaccination with Infanrix hexa and Prevenar 13, the subject experienced giant urticaria, hyperemic pharynx and fever (40 deg.C). This case was assessed as medically serious by GSK. The subject was treated with amoxicillin trihydrate (Amoxicillin) from 19 to 29 August 2011. On 28 August 2011, the events were resolved.

Company comment: Case of angioedema in a 5-month-old female subject less than 1 day after vaccination with Infanrix Hexa and Prevenar. The event resolved after 10 days of antibiotherapy. The context of pyrexia might have triggered the event.

In addition, one (1) case of Acute haemorrhagic oedema of infancy was received during the period:

- **B0743733A (Argentina) Acute haemorrhagic oedema of infancy, Malaise, Tachycardia, Purpura, Pyrexia, Rash, Toxic skin eruption.**

This case was reported by a physician and described the occurrence of acute hemorrhagic edema of infancy in a 7-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Relevant medical history was not reported. Previous and/or concurrent vaccination included pneumococcal vaccines (non-gsk) given on 20 August 2011. On 20 August 2011, the subject received 3rd dose of Infanrix hexa (unknown route of administration, unknown site of injection). On 21 August 2011, within hours of vaccination with Infanrix hexa, the subject experienced high fever, exanthema and malaise. On 21 August 2011, he was taken to the emergency room where he was diagnosed with acute hemorrhagic edema of infancy. On 22 August 2011, he was examined by his pediatrician who noticed that the subject was tachycardic. He also presented a purpuric exanthema, his fever persisted and he had edema of the four limbs. The doctor assumed that the subject had a toxicodermia and treated him with corticosteroids and antihistaminics. He controlled the subject 24 hours afterwards. He indicated evaluation by a dermatologist. The subject was not hospitalized. This case was assessed as medically serious by GSK. On 23 August 2011, the pediatrician reported that the subject responded well to the treatment. He had no fever and the edema has diminished. The purpuric lesions were fainter. Given the improvement of the subject, his mother did not consult a dermatologist. At the time of reporting, the events were improved. This case was closed since no additional information could be obtained.

Company comment: Hemorrhagic edema of infancy (fever exanthema and malaise) in a 7-month-old male subject (acute less than 1 day after 3rd dose of Infanrix hexa. Due to the lack of medical data, the time sequence and assessment of causality remain dubious.

6.5.2.11.2. Erythema multiforme

Two (2) cases of Erythema multiforme were received during the period:

- **D0069303A (Germany): Erythema multiforme**

This case was reported by a physician, via a web site, and described the occurrence of erythema exsudativum multiforme minor in a 9-month-old subject of unspecified gender who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccinations included pneumococcal vaccine (non-GSK) (Prevenar, Wyeth). The subject's medical history included mild schonlein-henoch purpura after an infection when being 7 months old. On an unspecified date approximately in July 2010, the subject received 3rd dose of Infanrix hexa (unknown route and application site), together with 3rd dose of Prevenar (unknown route and application site). One day after vaccination with Infanrix hexa and Prevenar, the subject experienced erythema exsudativum multiforme minor. Laboratory values and IgE were normal. This case was assessed

as medically serious by GSK. At the time of reporting, on 2 November 2010, the outcome of the event was unspecified. No further information will be available.

Company comment: A 9-month-old subject developed minor erythema multiforme after 3rd dose of Infanrix hexa. This case lacks data on the subject's medical history, data confirming the diagnosis (biopsy), and other possible diagnoses.

- **D0072847A (Germany): Erythema multiforme, Urticaria, Arthropod bite, Swelling, Erythema, Pyrexia, Hypertonia, Herpes simplex, Rash, General physical health deterioration**

This case was reported by a physician and described the occurrence of erythema exsudativum multiforme in a 2-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccine included rotavirus vaccine (RotaTeq). There were no concurrent medications, no concurrent medical conditions or any other risk factors. On 15 July 2011 the subject received 1st dose of Infanrix hexa (intramuscular, left gluteal). An unspecified time after vaccination the subject experienced urticaria. On 12 August 2011 the subject received 2nd dose of Infanrix hexa (intramuscular, left gluteal) and unspecified dose of RotaTeq (oral). In the evening the subject experienced fever. The subject was hospitalized from 17 August 2011 to 21 August 2011 because of parainfectious erythema exsudativum multiforme and differential diagnosis urticaria. The subject was admitted to hospital by the rescue service. The mother reported that the subject showed several mosquito bites in the morning. The subject was treated with zinc oxide and vileda. In the evening the subject's mother used chamomile bath for the first time. At admission to hospital the subject showed swelling and erythema on whole body. There was no shortness of breath. The subject was drinking well. The subject was in good nutrient condition and showed reduced general condition. There was no itching. Ear, nose and throat were bland. Urticarial maculopapular exanthema was on whole body with maximum on trunk. Flexion tone was increased. Internal and neurological examination was age-corresponding inconspicuously. Laboratory tests showed increased IgM values for Herpes II (9 U per ml). The subject was treated with intravenous infusion, intravenously with prednisolone and with cetirizine hydrochloride drops. The exanthema was intermittent. Because of herpes II serology finding the physician suspected erythema exsudativum multiforme. The subject was discharged from hospital on 21 August 2011 with improving exanthema. Latest on 24 August 2011 all events were resolved. On 20 September 2011 the subject received 3rd dose of Infanrix hexa (intramuscular, left gluteal) and unspecified dose of RotaTeq (oral). On the same day the subject experienced fever. From 24 September 2011 on the subject developed rash with increasing efflorescences. The subject was treated in emergency admission on 25 September 2011. Urticarial multiform exanthema was diagnosed as suspected vaccination reaction. The subject was treated with prednisolone acetate. In September 2011, the events were resolved. According to treating physician urticaria was unlikely related to vaccination with Infanrix hexa. No further information will be available.

Company comment: A 2-month-old subject developed erythema multiforme 5 days after 2nd dose of Infanrix hexa and RotaTeq. This case lacks data confirming the

diagnosis (biopsy), and other possible diagnosis. Conversely, a medical history of Herpes type II and recent mosquito multiple bites was noted. Causal relationship with the vaccination was unlikely.

6.5.2.11.3. Henoch-Schonlein purpura

Two (2) cases of Henoch-Schonlein purpura were received during the period:

- **B0710915A (France): Henoch-Schonlein purpura, Contusion**

This case was reported by a consumer and described the occurrence of rheumatic purpura in a 5-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. A physician or other health care professional has not verified this report. Concurrent medical conditions included a cold on 10 March 2011. First dose of Infanrix hexa associated with pneumococcal vaccine (Prevenar) was well tolerated. On 22 March 2011, the subject received a 2nd dose of Infanrix hexa (batch and route unknown, unknown thigh). On 27 March 2011, 5 days after vaccination with Infanrix hexa, the subject's mother noticed the presence of bruises on all vaccinated leg from knee to toes and on the other leg with a lower intensity (coded bruises on bilateral lower legs). At emergency service, where blood and urine analyses were performed (results not provided), the physician diagnosed a rheumatic purpura. According to the mother, the physician said that it was not very probable that rheumatic purpura was related to vaccination with Infanrix hexa and might be related to a virus infection. The subject was not hospitalized and was discharged without any treatment. On 04 April 2011, a few bruises persisted and purpura was clearly improved. This case was assessed as medically serious by GSK. At the time of reporting, the events were improved.

Company comment: Case of a possible Henoch-Schonlein purpura in a 5-month-old subject 5 days after 2nd vaccination with Infanrix and Prevenar. This case lacks laboratory confirmation of the diagnosis.

- **D0070216A (Germany): Henoch-Schonlein purpura, Thrombocytopenia, Petechiae, Pyrexia, Upper respiratory tract infection, Anaemia**

This case was reported by a physician, via a sales representative, and described the occurrence of Schoenlein-Henoch purpura in a nearly 9-month-old subject of unspecified gender who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. The subject was born as hypoplastic neonate with cyanosis and hypoglycaemia, after treatment with ampicillin due to premature rupture of the amnion. The subject's family were smokers. Former vaccinations were well tolerated. On 1 April 2010 the subject received 3rd dose of Infanrix hexa (intramuscular, left thigh). On an unspecified date in April 2010 the subject developed generalised exanthema and fever of 39 degC. On 29 April 2010 the subject was hospitalised with Schoenlein-Henoch purpura and thrombocytopenia. At the time of reporting all events were resolved. After the next vaccination with Infanrix hexa the events did not recur. The physician considered

CONFIDENTIAL

CONFIDENTIAL

Schoenlein-Henoch purpura and thrombocytopenia were probably related to vaccination with Infanrix hexa. The subject was hospitalised from 29 April to 03 May 2010. According to the hospital report, the subject was diagnosed with thrombocytopenia and infection of the upper airways. When admitted to hospital the subject had petechial exanthema and mild fever. There was no previous infection. The subject had no cough, diarrhea, vomiting or denial of food. The subject had thrombocytopenia with an initial platelet count of 21 Gpt/L. This increased to 98 Gpt/l in further course without treatment. There was a mild initial anemia, but haemoglobin and hematocrit values increased in further course. Additionally a mildly increased c-reactive protein (CRP) was found. The subject was treated with ibuprofen and fluoride + Vitamin D (Zymafluor D). When the subject was discharged, the events were nearly resolved.

Company comment: A nearly 9-month-old subject experienced HSP with 3rd dose of Infanrix Hexa. The subject had an upper respiratory infection prior to this event. The case lacks other laboratory data (antibody testing, plasma D-dimers, PT, etc) to confirm the diagnosis.

6.5.2.11.4. *Petechiae*

Twenty nine (29) cases of Petechiae were reported during the period, out of which 20 cases were quoted as serious. In 11/20 serious cases a haematologic disorder was associated: (Idiopathic or non specified) thrombocytic purpura (n=7), thrombocytopenia (n=.3), hemorrhagic diathesis (n=1). These cases are summarized in [Table 26](#).

Table 26 Summary of cases of Petechiae received during the period

6.5.2.11.5. Purpura

Three (3) cases of Purpura were received during the period:

- **B0705315A (France): Purpura, Pyrexia, Injection site erythema, Injection site oedema, Injection site induration, Rash macular.**

This case was reported by a pharmacist and a physician and described the occurrence of fever in a 16-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Previous vaccinations with such type of vaccine were well tolerated. On 03 March 2011, the fourth dose of Infanrix hexa was administered intramuscularly in unknown thigh (probably the right). On 07 March 2011, the subject received a booster dose of Infanrix hexa (batch A21CA784A, route and injection site unknown). Twelve hours later, the subject experienced severe fever (40-41 degrees Celsius) during 24 hours, mild induration at injection site during 3 days and mild petechial purpura of extremities associated with erythematous macules (coded rash erythematous macular) which lasted 3 days. On 10 March 2011, platelets were at 217000/mm³. The subject was treated with paracetamol (Doliprane). The reporter considered that the events were clinically significant (or requiring intervention) and resolved. The reporter considered the events as almost certainly related to vaccination with Infanrix hexa.

- **B0743959A (Italy): Purpura.**

This case was reported by a regulatory authority (IT-Agenzia Italiana del Farmaco # 146768) and described the occurrence of purpura in a 3-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevenar 13) for prophylaxis. On 18 May 2011, the subject received unspecified dose of Infanrix hexa (unknown administration route, unspecified injection site) and unspecified dose of Prevenar 13 (unknown administration route, unspecified injection site). On 18 May 2011, less than one day after vaccination with Infanrix hexa and Prevenar 13, the subject experienced purpura on face and extremities. At the time of reporting, the outcome of the event was unspecified. No more information was expected. Therefore, this case has been closed.

- **B0743733A (Argentina) Acute haemorrhagic oedema of infancy, Malaise, Tachycardia, Purpura, Pyrexia, Rash, Toxic skin eruption**

See Section [6.5.2.11.1](#) Angioderma.

6.5.2.11.6. Subcutaneous nodule

Two (2) non-serious cases of Subcutaneous nodule were received during the period:

- **B0740908A (Poland): Injection site reaction, Subcutaneous nodule.**

This case was reported by a physician and described the occurrence of injection site reaction in a 4-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline) for prophylaxis. No adverse event was reported after the two previous doses of Infanrix hexa. On 21 July 2011, the subject received 3rd dose of Infanrix hexa (intramuscular, unknown injection site). On 22 July 2011, 1 day after vaccination with Infanrix hexa, the subject experienced injection site reaction (3cm diameter). On 15 August 2011, injection site reaction resolved. 3 weeks after vaccination with Infanrix hexa, a subcutaneous hard nodule (5x10cm) was perceptible on injection site. At the time of reporting the outcome of the subcutaneous hard nodule was unspecified. The physician reported that the injection site reaction was almost certainly related to vaccination with Infanrix hexa.

- **B0745076A (France): Subcutaneous nodule, Injection site pruritus, Injection site eczema, Injection site induration, Injection site nodule.**

This case was reported by a dermatologist and described the occurrence of subcutaneous nodule in a two-year-old subject of unspecified gender who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), combined diphtheria, tetanus, acellular pertussis and inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrixquinta) for prophylaxis. Medical history and concurrent medications were unspecified. On an unspecified date, the subject received 1st dose of Infanrix Hexa (unknown batch, route and injection site). One month later, on an unspecified date, the subject received 2nd dose of Infanrix Quinta (unknown batch, route and injection site). One month later, on an unspecified date in 2011, the subject received 3rd dose of Infanrix Hexa (unknown batch, route and injection site) (inappropriate age at vaccine administration). In 2011, three weeks after vaccination with Infanrix Hexa, the subject experienced pruritus and eczematiform aspect at injection site with subcutaneous nodules. At the time of reporting, the events subcutaneous nodule, injection site pruritus and injection site eczema were unresolved. Causality assessment was not provided. Upon follow-up received on 27 September 2011: First dose of Infanrix hexa was administered on 09 November 2010 intramuscularly in left thigh. On 02 August 2011, an ultrasound scan showed an aspect of an unspecified fibrous granuloma (coded injection site granuloma) on 10 cm with scratching lesions. At the time of reporting, events were improved and Infanrix hexa was not readministered. The dermatologist considered the events were almost certainly related to vaccination with Infanrix hexa.

6.5.2.11.7. Urticaria, Urticaria papular and Urticaria thermal

Sixty seven (67) cases of Urticaria/Urticaria papular/Urticaria thermal were received during the period, out of which 18 were serious. Summary information for the complete set of reports is shown in [Table 27](#) and [Table 28](#). These tables also include one case received prior to the period of this report but never included in a previous PSUR (D0066224A). This case's ID is marked by a '*' in [Table 28](#).

Table 27 Summary of information complete data set (n=68)

Patient age (n=65)	Range	months	2-33

6.5.2.12. Vascular disorders**6.5.2.12.1. Circulatory collapse**

Seven (7) cases of Circulatory collapse were received during the period:

- **B0698663A (Italy): Anaphylactic reaction, Circulatory collapse, Slow response to stimuli, Cyanosis, Hypotonia, Hypothermia, Pallor, Bradycardia, Oxygen saturation decreased, Pyrexia.**

See Section 6.5.2.6.2 Anaphylactic/Anaphylactoid reaction and Drug hypersensitivity.

- **B0713106A (Netherlands): Circulatory collapse, Cyanosis, Pallor**

This case was reported by a regulatory authority (NL-College ter Beoordeling van Geneesmiddelen # NL-LRB-116677) and described the occurrence of circulatory collapse in a 12-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevenar) for prophylaxis. No concomitant medication was reported. The subject had no known past drug therapy and had no known medical history. On 4 November 2010 the subject received unspecified dose of Infanrix hexa (intramuscular, unknown site of injection, batch number not provided) and unspecified dose of Prevenar (intramuscular, unknown site of injection, batch number not provided). On 4 November 2010, 22 hours after vaccination with Infanrix hexa and Prevenar, the subject experienced circulatory collapse with blue lips and pallor. When the subject was taken out of the bed, he recovered rapidly. This case was assessed as medically serious by GSK. The regulatory authority reported that the events were probably related to vaccination with Infanrix hexa and Prevenar. Further details will be provided by the Reporting Authority whenever available.

Company comment: Case of near SUDI in a 12-month-old male subject 22 hours after combined vaccination with Infanrix hexa and Prevenar. The event resolved after stimulation.

- **D0069341A (Germany): Circulatory collapse, Apnoea, Loss of consciousness, Pallor, Bradycardia, Salivary hypersecretion, Cyanosis, Epilepsy, Partial seizures, Foaming at mouth, Hypotonia, Cardiac arrest, Vomiting, Dyskinesia, Eye movement disorder, Productive cough, Depressed level of consciousness, Hypokinesia, Bronchitis**

See Section 6.5.2.2.2 Cardiac arrest.

- **D0069460A (Germany): Circulatory collapse, Apathy, Pallor, Asthenia, Heart rate decreased, Screaming, Staring**

This case was reported by a physician, via a sales representative, and described the occurrence of apathy in a 3-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated

poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccination included pneumococcal vaccines (Prevenar 13, Pfizer). On 14 October 2010 the subject received 1st dose of Infanrix hexa (unknown route and injection site) and contralaterally Prevenar 13 (unknown route and injection site). Minutes after vaccination, after the child screamed shortly, he experienced fixed gaze, and was weak and very pale (grey face colour). The subject was breathing spontaneously. Oxygen was administered. The emergency physician admitted the subject to the hospital. The subject was observed for 24 hours with no new findings. After that the subject was feeling well. Concurrent medications included Ergocalciferol (Vigantoletten). There were no concurrent medical conditions or any other risk factors. The next vaccination with Infanrix hexa and Prevenar 13 took place in hospital with monitoring of circulation. The events did not recur. The physician considered the events were probably related to vaccination with Infanrix hexa. All events were resolved.

Company comment: Case of circulatory collapse in a 3-month-old male subject minutes after 1st vaccination with Infanrix hexa and Prevenar. The event resolved after oxygen therapy. No new event after monitored 2nd vaccination.

- **D0070901A (Germany): Circulatory collapse, Respiratory arrest, Cyanosis, Hypotonic-hyporesponsive episode, Screaming, Agitation, Hypotonia, Peripheral coldness, Ill-defined disorder, Fatigue, Pyrexia**

See Section 6.5.2.10.3 Respiratory arrest.

- **D0071446A (Germany): Hypotonic-hyporesponsive episode, Circulatory collapse, Apathy, Pallor**

This case was reported by a physician and described the occurrence of hypotonic-hyporesponsive episode in an 8-week-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and pneumococcal vaccine (non-gsk, Prevenar) for prophylaxis. On 15 April 2011 the subject received the first dose of Infanrix hexa ((batch number A21CB071A, unknown thigh) together with the first dose of Prevenar (other thigh). Six hours after vaccination, the subject fell pale, collapsed and became apathic. The subject was hospitalised. The patient had completely recovered at the time of reporting. Follow-up information was received on 27 May 2011 via another manufacturer (PFIZER-INC, DE-PFIZER-INC-2011108012). The following narrative was provided: "The reporting physician was informed by the patient's mother that after vaccination the patient has collapsed. This collapse was described as follows: When the patient's father arrived at home he noticed that the patient was "snow-white". When he then picked up his child the patient's head fell to the side. The patient was still awake but seemed to be apathic. The parents immediately went to a local hospital. However, in hospital no physical examination was performed but the clinician only stated to the parents: "No wonder after receiving the vaccines".

Company comment: Case of possible circulatory collapse in an 8-week-old male subject 6 hours after 1st combined vaccination with Infanrix hexa and Prevenar. The event was resolved after stimulation. No further examinations were performed.

- **D0072852A (Germany): Circulatory collapse, Sepsis, Shock, Crying, Pallor**
Ses Section 6.5.1 Cases with a fatal outcome.

6.5.2.12.2. Kawasaki's disease

Three (3) cases of Kawasaki's disease were reported during the period:

- **B0691861A (Italy): Kawasaki's disease, Rash maculo-papular, Diarrhoea, Pyrexia, Cheilitis, Skin exfoliation, Oedema peripheral, Erythema**

This case was reported by a regulatory authority (IT-Agenzia Italiana del Farmaco # 130459) and described the occurrence of Kawasaki's disease in a 2-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine. (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prenar) for prophylaxis. Concurrent medical conditions included G6PD deficiency, conjunctivitis and upper respiratory tract infection. On 11 November 2010 the subject received unspecified dose of Infanrix hexa (intramuscular, unknown), unspecified dose of Prenar (intramuscular, unknown). On 13 November 2010, 2 days after vaccination with Infanrix hexa and Prenar, the subject experienced maculo-papular exanthema on trunk, spreading to the whole body and face, diarrhea and high fever. On 14 November 2010, the baby was hospitalised due to these symptoms. After 4 days of hospitalisation, the baby presented cheilitis, perianal desquamation, pedal edema and erythema of soles of feet with persisting fever. Kawasaki disease was suspected. Relevant test results included ECG (normal), chest X-ray on 16 November 2010 and 21 November 2010 (both negative), echocardiogram (mild pericardial effusion), ultrasound of the abdomen (mild fluids below liver and behind bladder as well as troponin (normal). The subject was treated with antibiotics, anti-inflammatory (Antiinflammatory), IgG (IV, 20 unt/kg) and dipyridamole (Dipiridamol). At the time of reporting the outcome of the events was unspecified. The regulatory authority reported that the events were possibly related to vaccination with Infanrix hexa and Prenar.

Company comment: Kawasaki's disease in a 2-month-old male subject 2 days after combined vaccination with Infanrix Hexa and Prevenar.

- **D0070921A (Germany): Kawasaki's disease, Pyelonephritis, Pyrexia, Infection, Somnolence, Fluid intake reduced, General physical health deterioration, Pallor, Ill-defined disorder, Rash, Conjunctivitis, Erythema, Enanthema, Chapped lips, Hypertrophy of tongue papillae**

This case was reported by a physician via regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011009954) and described the occurrence of Kawasaki syndrome in a 2-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. According to completed questionnaire, signed on 23 March 2011, on 28 February 2011 the subject received 1st dose of Infanrix hexa (intramuscular, left thigh). On 03 March 2011, 3 days after vaccination with Infanrix hexa, the subject

experienced Kawasaki's syndrome for several days. Diagnose was based on clinical symptoms and exclusion of other causes for fever after puncture of cerebrospinal fluid and urinary bladder. By differential diagnosis, sepsis, meningitis and urinary tract infection have been excluded. The subject was hospitalised and the reporter reported that the events were life threatening. In March 2011, the event was resolved. According to provided hospital report from paediatric unit, signed on 17 March 2011, the subject was hospitalised from 02 to 11 March 2011. Kawasaki's syndrome and haemangioma were diagnosed. The subject's medical history included premature baby (after 34th weeks of pregnancy). She was a twin. Postpartal the subject developed streptococcal infection, which was treated. Concurrent medical conditions included congenital hemangioma at back and forehead. There were no concurrent medical conditions, no continuous medications and no known allergies. On 28 February 2011 the subject received 1st dose of Infanrix hexa. On 28 February 2011 in the evening, the subject experienced fever with a body temperature up to 39.3 degC. The subject was treated with paracetamol on 28 February or 01 March 2011 in the evening and on 01 March or 02 March 2011 in the morning. Since 28 February 2011, the subject was sleeping a lot (sleepiness) and drinking less (fluid intake reduced). Blood examination showed increased value of C-reactive protein (75 mg/L). By examination of urine via test strip, leucocytes were shown. The subject was hospitalised due to unclear highly febrile infection and suspected pyelonephritis. On admission examination, the subject was in reduced general condition. Skin coloration was mildly pale (paleness of skin). There were no signs for meningism. Values of inflammation were shown to be distinctly increased. Initially, urinary tract infection was suspected due to unusual urine test of urine bag. Puncture of bladder showed very low increased leukocyte count (15/mcl). Puncture of liquor showed also normal values. The subject was treated with cefotaxime (Cefotaxim) and mezlocillin. On the following day, the subject developed increasing exanthema on whole trunk and in further course non-purulent conjunctivitis, erythema at palmar and plantar as well as a distinct enanthema with chapped lip and hypertrophy of tongue papillae. During treatment with antibiotics, fever remained. Due to clinical signs and fever, Kawasaki's syndrome was suspected. The subject was treated with normal immunoglobulin (Immunoglobulin) two times (2 g/kg body weight). Treatment with antibiotics was discontinued. Symptoms improved, fever resolved. By echocardiography, no coronary aneurism could be detected. The subject was treated with aspirin (ASS, 3-5 mg/kg body weight/d) for prophylaxis. During hospitalisation, small haemangioma at forehead and a bigger one at back were treated with cryosurgery (Cryotherapy). Symptoms resolved and subject was discharged in good general condition.

Company comment: Kawasaki's disease in a 2-month-old female subject 3 days after 1st dose of Infanrix hexa. No cardiovascular findings were reported. The subject was hospitalized and the event resolved after treatment with immunoglobulins.

- **D0071621A (Germany): Kawasaki's disease, Meningitis, Leukocytosis, Pericarditis, Mitral valve incompetence, Pyrexia, Fluid intake reduced, General physical health deterioration, Rash maculo-papular, Fungal skin infection, Cheilitis, Chapped lips, Palmar erythema, Lymphadenopa.**

This case was reported by a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011017683) and described the occurrence of atypical kawasaki disease in an nearly 12-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccination included pneumococcal vaccines (non-gsk) (Prevenar 13, Pfizer). Previous vaccination included 1st dose of Infanrix hexa and Prevenar 13 (each unknown route and application site) given on 16 August 2011, which was well tolerated. On 2 November 2010 the subject received 2nd dose of Infanrix hexa and 2nd dose of Prevenar 13 (each unknown route and application site). At an unspecified after 2nd vaccination with Infanrix hexa and Prevenar 13, the subject experienced fever with a body temperature up to 38.2 degC. On 6 May 2011 the subject received 3rd dose of Infanrix hexa and 3rd dose of Prevenar 13 (each unknown route and application site). On 9 May 2011, 3 days after 3rd vaccination with Infanrix hexa and Prevenar 13, the subject experienced atypical Kawasaki disease. The subject developed fever with body temperatures up to 40 degC. On 11 May 2011, the subject developed exanthema on abdomen and back. Exanthema of mycotic cause was suspected. The subject was treated symptomatically with antipyretic (Antipyretics). On 12 May 2011, the subject's fluid intake was reduced. His general condition was reduced. The subject was treated with cefpodoxime. Symptoms did not improve. On 13 May 2011 the subject was hospitalised. Atypical Kawasaki syndrome, secondary meningitis and pericarditis were diagnosed. He showed maculo-papular exanthema at trunk, arms, legs and face. His lips and palms were reddened. Cervical lymph nodes were enlarged. His body temperature was up to 40.3 degC. Initially, there were clearly increased parameters for an infection (signs of infection) as well as distinct exanthema. Culture of blood and liquor were uneventfully. Due to abnormal midstream urine, the subject was treated with cefuroxime sodium (Cefuroxim). Fever did not resolve. On 18 May 2011, the subject still suffered from fever. He showed chapped lips, palmar erythema, leukocytosis and mild cervical lymphadenopathy. Kawasaki's disease was suspected. The subject was treated with normal immunoglobulin (Immunoglobulin) and aspirin (Acetylsalicylic acid). Fever resolved and general condition improved. On 20 May 2011, echocardiography showed pericarditis and mitral insufficiency. On 24 May 2011, the subject was discharged from hospital after 12 days. At the time of reporting atypical Kawasaki disease was unresolved. The reporter reported that the events were life threatening. No further information will be available.

Company comment: Kawasaki's disease in 12-month-old male subject 3 days after 3th dose of Infanrix hexa and 2nd dose of Prevenar. The subject was hospitalizend and the event resolved after treatment with immunoglogulins and aspirin.

6.6. Follow-Up Data

Relevant follow-up information received during the period on fatal cases subsequent to their inclusion in PSUR 14 (B0580597A) and PSUR 15 (B0605003A and B0608494A) is mentioned in ***bold italic*** below. This information was taken into account for the observed-to-expected analysis of sudden deaths as provided in Section 9.3.1.1. CIOMS forms are presented in APPENDIX 5B.

- **B0580597A (Netherlands) Sudden infant death syndrome, Depressed level of consciousness, Hypotonia, Pallor**

This case was reported by a healthcare professional and described the occurrence of death not otherwise specified in a 2-month-old female who was vaccinated with a 1st dose of Infanrix hexa and Prevenar. The subject had no medical history and no concomitant medication. One day after vaccination the subject was found in bed nonresponsive, floppy and pale. The subject died on 17 June 2009, cause of death was not reported. The autopsy report already received has confirmed SUDI. **The regulatory authority considered the events were unlikely to be related to vaccination with Infanrix hexa and Prevenar.**

- **B0605003A (Italy): Sudden death, Cardiac arrest, Convulsion, Hypokinesia.**

This case was reported by the Italian regulatory authority and described the occurrence of cardiac arrest in a 2-month-old female who was vaccinated with an unspecified dose of Infanrix hexa on 10 August 2009. Less than one day after vaccination, the subject experienced convulsions. The subject was hospitalised from 14 August until 19 August 2009. At the time of reporting, the event was resolved with sequelae. Last convulsion episode was on 18 October 2009. The baby showed a regular growth but a light motor retardation in respect of the age. Her weight was 7.10 kg. Diagnostic tests as karyotype, ultrasonography, computerized axial tomography and nuclear magnetic resonance were negative. She was treated with Luminalette. The subject died due to a cardiac arrest ~~at an unspecified time after vaccination~~ **on 5 March 2010. After autoptic exam, the physician reported that the convulsions and cardiac arrest were unrelated to vaccination with Infanrix hexa. The autopsy report confirmed that the event was a suddenly death with no specified cause.**

Company comment: Case of Sudden Unexpected Death in Infancy (SUDI). The subject had a history of convulsions since 2-months of age, which started less than one day after vaccination with Infanrix hexa.

- **B0608494A (Netherlands): Sudden infant death syndrome, Depressed level of consciousness, Mouth haemorrhage, Nasopharyngitis**

This case was reported by a healthcare professional and described the occurrence of cot death in a 14-week-old male who was vaccinated with the 2nd dose of Infanrix hexa and Prevenar on 12 November 2009. The child was born at term and weighed 4120 g. The child had a history of viral infection before vaccination with the 1st dose of Infanrix hexa and Prevenar. In the beginning of November, 2 weeks before death, the subject had a common cold. The subject did not experience any adverse events

CONFIDENTIAL

CONFIDENTIAL

after vaccination. Four days after vaccination with Infanrix hexa and Prevenar, the subject was brought to day care centre. He had no fever. He burped well after being fed and was put into bed at 9:25 lying on the abdomen (with permission of the mother) and he was being checked every 20 minutes. At 12:00, the subject was nonresponsive and had blood in his mouth. Reanimation was started immediately and the child was admitted to hospital. The child died on 16 November 2009 from sudden infant death syndrome. An autopsy was performed and did not reveal any cause of death found in autopsy or on toxicological investigation. ***Tryptase: 4.2 mcg/l blood from heart (normal: lower than 11.5 mcg/l for adults). No indication for anaphylactic reaction. In addition, time period of 4 days considered too long to suspect an anaphylactic reaction. No indications for a relation with vaccinations.***

Company comment: *The subject had viral infections as medical history. No cause of death found in autopsy or toxicological investigation. Anaphylactic reaction was excluded.*

7. STUDIES

In line with the Addendum to ICH E2C [2], only studies with findings that have potential impact on product safety information are included in Sections 7.1, 7.3 and 7.4.

7.1. Newly-Analysed Studies

No study assessing Infanrix hexa was completed during the period. No change to the RSI is warranted.

7.2. Targeted Safety Studies

This section provides an update on any planned, ongoing or completed targeted safety studies involving Infanrix hexa in the reporting period. Targeted safety studies are those specifically planned or conducted to examine an actual or hypothetical safety concern (Vol 9A, Section 6.3.8.b) in a product marketed anywhere in the world. This includes any GSK-sponsored, and when applicable, GSK-supported pharmacoepidemiology study or clinical trial conducted anywhere in the world with the aim of identifying or quantifying a safety hazard. Although all clinical trials collect safety information as a matter of routine, only those initiated to examine a specific safety concern are considered a targeted safety study.

No targeted safety study was planned, ongoing or completed for Infanrix hexa.

7.3. Other Safety Studies

The following ongoing studies are not targeted safety studies but are also considered of interest as they may provide useful new information on the safety profile of Infanrix hexa:

- **103506 (DTPA-HBV-IPV-118 PRI)** A phase IV, non-randomised, open-label, multi centre study with two parallel groups to assess the immunogenicity and safety of GlaxoSmithKline (GSK) Biologicals combined DTPa-HBV-IPV/Hib vaccine administered as a three-dose primary vaccination course at 2, 4 and 6 months of age in healthy infants in Canada.
- **113948 (DTPA-HBV-IPV-124 PRI)** A phase II, double-blind, randomized, multicentre study to evaluate the safety and immunogenicity of new formulations of GlaxoSmithKline Biologicals DTPa-HBV-IPV/Hib vaccine when administered to healthy toddlers as a booster dose at 12 to 15 months of age.
- **114843 (DTPA-HBV-IPV-125 BST:124)** A phase II, double-blind, randomized, multicentre study to evaluate the safety and immunogenicity of new formulations of GlaxoSmithKline Biologicals DTPa-HBV-IPV/Hib vaccine when administered to healthy toddlers as a booster dose at 12 to 15 months of age.

7.4. Published Safety Studies

A full review of the literature was conducted during the reporting period. Useful information was published during the period concerning:

- a. safety and reactogenicity of Infanrix-IPV+Hib and Infanrix hexa (Lim, 2011). Both vaccines were well tolerated and substitution of DTPa-IPV/Hib with Infanrix hexa at Month 5 reduced the number of injections required at this age by one.
- b. immunogenicity and safety of co-administration of Infanrix hexa with an investigational tetravalent meningococcal serogroups A, C, W-135 and Y-tetanus toxoid conjugate vaccine (ACWW-TT; Knuf, 2011). Pre-specified criteria for non-inferiority of immunogenicity following co-administration versus separate ACWY-TT and Infanrix hexa administration were reached, and the safety profile of co-administration was similar to that of Infanrix hexa alone.

These studies did not highlight any safety issue.

8. OTHER INFORMATION

8.1. Efficacy Related Information

Sixty two (62) cases suggesting potential lack of efficacy were received during the period and included at least one of the following MedDRA Preferred Terms: Pertussis (n=41), Bordetella test positive (n=2), Meningitis haemophilus (n=4), Haemophilus infection (3), Hepatitis B antibody negative (n=3), Therapeutic response decreased (n=1), Meningitis (3), Vaccination failure (n=48). These preferred terms were suggestive of lack of efficacy of the Pertussis, Hib and/or the Hepatitis B component.

8.1.1. Pertussis component

Forty-three (43) cases including the event Pertussis (n=41) or Bordetella test positive (n=2) were identified during the reporting period. Out of 41 cases including the event Pertussis, 34 were reported with a MedDRA Preferred Terms vaccination failure. These cases are summarized in Table 29.

Out of the 43 cases, there were 23 female subjects and 15 male subjects; in 5 cases gender was unknown. The age of the subjects ranged from 5 months to adult. There were 39 cases reported as serious and 4 as non-serious. In 9 cases the outcome of the event was reported as improved, resolved in 8 cases, unknown and unresolved at the time of report in 4 cases. Time to onset ranged between 5 months and 5 years.

In 27 of these cases, subjects had Pertussis diagnosis confirmed by laboratory test and 16 were not laboratory confirmed. Two of the 27 laboratory-confirmed cases were asymptomatic, and the 25 symptomatic and laboratory confirmed case all received a complete vaccination schedule.

During the previous 1 year period, GSK received 13 potential lack of efficacy cases. The observed increase in the number of potential Pertussis component-related lack of efficacy reports is concurrent to the increase in number of cases received specifically from Germany (38 during the current period compared to 12 during the previous period).

Table 29 Summary of cases of potential pertussis component-related lack of efficacy received during the period

8.1.2. *Haemophilus influenza* type b component

Seven (7) cases including the preferred terms Meningitis haemophilus (4) or Haemophilus infection (3) were received during the period. Four were reported from Australia. All were serious. The preferred term Vaccination failure was reported in all cases. These cases are summarized in [Table 30](#).

Table 30 Summary of cases of potential Hib component-related lack of efficacy received during the period

8.1.4. Conclusion of cases of potential lack of efficacy

During the period of this PSUR, 62 cases were identified where the MedDRA Preferred Terms could potentially correspond to a lack of effect of the Hib, pertussis or hepatitis B component.

Table 32 shows the number of cases and respective reporting frequencies as reported during this PSUR and the previous PSUR periods.

Table 32 Reporting rate of potential lack of efficacy cases

	PSUR #15		PSUR#16	
	Number of cases	Reporting rate per 100 000 doses distributed	Number of cases	Reporting rate per 100 000 doses distributed
Pertussis	21	0.18	43	0.35
Hib	6	0.05	7	0.06
Hepatitis B	1	0.01	3	0.02

There has been no unusual level of reports of lack of efficacy regarding the Hib and Hepatitis B components. The reporting rate for potential Pertussis component related lack of efficacy has increased by 94%.

CONFIDENTIAL

8.2. Late-breaking information

One new fatal case (B0762668A) was received after the data lock point as well as new follow-up data for one of the fatal cases described in Section 6.5.1 (D0072852A). The latest CIOMS forms for these cases are attached in APPENDIX 5C.

- **B0762668A (Belgium) Sepsis, Pyrexia, Diarrhoea**

This case was reported by a pharmacist and by another health professional and described the occurrence of septicemia in a 3-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), live attenuated human rotavirus vaccine (Rotarix) and pneumococcal vaccines (non-gsk) (Prevenar) for prophylaxis. The subject was a premature baby. Concurrent medical conditions included cold. On 13 October 2011, the subject received 1st dose of Infanrix hexa (route and injection site unknown, batch number not provided), 1st dose of Rotarix (route unknown, batch number not provided) and 1st dose of Prevenar (route and injection site unknown, batch number not provided). On 21 October 2011, 8 days after vaccination with Infanrix hexa, Prevenar and Rotarix, the subject experienced fever and diarrhea. The subject was hospitalised. The subject died in the night 21 and 22 October 2011 from septicemia. It was unknown whether an autopsy was performed. The subject's twin sister had received the same vaccination without problem. Information inadvertently not recorded in the initial report: The event septicemia was added. Follow-up information received on 30 November 2011 and 2 December 2011 from 2 newspapers and from a consumer via a web forum: The mother's medical history included allergy and the family history included baby sudden death. The organisation who administered the vaccines was not aware that the subject had a cold. When the subject developed fever (39.9 deg.C) on 21 October 2011, the subject was treated by her parents with an antipyretic drug (suppository) and was taken to the hospital. At the hospital, gastroenteritis was firstly diagnosed, and after this diagnosis was changed to a pulmonary infection. The subject was treated with an antibiotic. But at 11 pm, her body was covered with purpura. The subject died at about 3 o'clock in the morning on 22 October 2011, 9 hours after she arrived at the hospital. Her body was covered with blue plaques. The diagnosis of purpura fulminans reported. The consumer also reported that rapid meningococcal meningitidis was mentioned, but no lumbar puncture and no hemoculture were performed therefore they could not conclude to this diagnosis. The subject's parents lodged a complaint against "X" because of the lack of information provided before the vaccination about the risks and the lack of precaution taken regarding the family history. The subject's twin sister of this case also experienced an adverse event after vaccination with same vaccines. Please see case B0767303A for details about the subject's twin sister.

Company comment: Death of a 3-month-old female subject due to septicaemia 8 days after combined 1st vaccination with Infanrix hexa, Rotarix and Prevenar. The subject's twin sister had received the same vaccination without problem. It is unknown whether an autopsy was performed.

- **D0072852A (Germany) Circulatory collapse, Sepsis, Shock, Crying, Pallor**

Data received after the data lock point: An autopsy was performed on 23 September 2011. Death was identified as respiratory failure with protracted shock due to interstitial pneumonia, probably of viral origin. Pathogenic microorganisms were not detected. There was no reaction at the injection site. Follow-up received on 12 December 2011 included a complete hospital report. The subject was hospitalized on 21 September 2011 at 09:30. In hospital the subject was diagnosed with death after ventricular tachycardia with hyperkalemia and acute circulatory shock of unclear genesis with anuria and hyperkalemia. Childhood examination U4 (performed in 3rd to 4th month of life) showed anemia (hemoglobin 8.5 g/dl). The subject's mother had arterial hypertension and received bisoprolol. She formerly underwent surgery because of wrong lung vein ostium. After the subject had received the vaccinations, there was nothing abnormal during the day. In the night, around 01:00 o'clock the subject had been drinking about 200 ml. At 03:00 the subject started crying, which increased despite treatment with simethicone (Sab). He was vomiting twice. There was a transient improvement after receiving caraway suppository at 05:00. In the morning the subject became pale with strange breathing. When hospitalized, the subject was in bad condition, with circulatory depression, tachycardia with heart rate over 210 per min, pallor, muscle hypotonia, high irritability, moaning breathing. Green stool was excreted once. Supraventricular tachycardia could be excluded by electrocardiogram (ECG), which showed sinus tachycardia. Blood gas analysis showed acidosis with increased lactate and potassium. The subject received volume bolus via infusion on the head. After sudden worsening of condition with fall in oxygen saturation the subject received ketamine and diazepam. There was a short phase of bradycardia with the need for cardiac massage. The subject received further volume via intra-osseous access, as well as dobutamine, adrenaline (Adrenalin), claforan for suspected sepsis and hydrocortisone for circulatory support. Echocardiogram excluded dilated cardiomyopathy, but showed reduced pump function of heart. Sonogram of head excluded acute bleeding. Abdominal sonogram was normal. The subject's body temperature had decreased to 33.1 degC rectal and exogenous warmth treatment was started. Blood test results challenged the diagnosis of sepsis, without fever and with no relevant inflammatory signs. Ammonia was increased, which was considered a possible sign for metabolic disorder. The subject received central vein catheter in V. jugularis interna and arterial catheter in V. femoralis at the right, but no stabilization could be achieved. Katecholamines were increased. The subject still had no diuresis and was treated with frusemide (Lasix). In further course the subject developed increasing potassium values, T-wave elevation, ventricular tachycardia, anuria and no improvement of the situation. Further treatment was without success. At 16:20 further cardiac problems developed, but because of the bad situation no defibrillation was started. The subject died at 16:21 in the parent's presence. The hospital physician stated that after exclusion of cardiac, cerebral and abdominal causes, the event was most likely an atypical sepsis without fever and inflammatory signs. However, postmortal cultures of blood and cerebrospinal fluid also showed no germs. Despite of the autopsy results, the cause of death still kept unclear for the hospital physician. He stated that there were no radiologic signs for pneumonia and artificial respiration had been successful, with normalization of blood gas values. A metabolic disorder was considered possible, but

it was more likely that lactic acidosis and hyperammonia were a secondary effect of shock.

Company comment: Death was identified in the autopsy as respiratory failure with protracted shock due to interstitial pneumonia, probably of viral origin. The cause of death in the autopsy and the hospital report were not congruent.

8.3. EU Risk Management Plan

There is no specific risk management plan in place for Infanrix hexa

8.4. Benefit Risk Analysis

During the PSUR reporting period, no separate risk-benefit analysis has been conducted.

9. OVERALL SAFETY EVALUATION

9.1. Signal Management

GSK employs a routine, pro-active process for identifying safety signals² with three main components:

1. Ongoing awareness and review of important individual cases, including all reports with a fatal outcome.
2. Systematic, regular and proactive review of aggregate safety data. This includes trend analysis to detect increased frequency of reporting and quantitative methodologies to detect signals.
3. Systematic, regular review of the literature.

A holistic approach is used so that all relevant data sources are interrogated when evaluating safety signals e.g. external sources, clinical studies, epidemiological studies, pre-clinical information.

All signals identified are evaluated; however, priority is given for serious events, particularly events reported with disproportionately high frequency, DMEs³, and events that if found to be causally related to the vaccine could significantly affect the benefit-risk profile.

Following evaluation of the signal, appropriate action is agreed. The options include continuing routine proactive pharmacovigilance, defining further work to better understand the risk, or recommendation of a label change and/or amendment to the Risk Management Plan (RMP).

² A safety signal is defined as a report or reports of an event with an unknown causal relationship to vaccination that is recognised as worthy of further exploration and continued surveillance (CIOMS VI).

³ Designated Medical Events: medically important events that are generally associated with drug toxicity.

GSK is able to detect issues of potential concern promptly and, where appropriate, communicate them expeditiously to regulators outside the PSUR process. Actions taken on these issues are then reflected in the PSUR to ensure information is communicated appropriately to all regulatory authorities.

Table 33 presents the reporting frequency of the 10 most frequently reported events for Infanrix hexa arising from spontaneous reporting including regulatory and consumer reports. For this analysis both serious and non-serious events reported were taken into account, from launch (23 October 2000) up to the data lock point of this safety update report. Listed events (according to RSI version 10) are in bold.

Table 33 Overview of the 10 most frequently spontaneously reported events for Infanrix hexa.

Event SOC	Event PT	Number Of Events ¹	Reporting frequency per 100,000 doses distributed
General disorders and administration site conditions	Pyrexia	4207	5.77
Nervous system disorders	Crying	1300	1.78
General disorders and administration site conditions	Injection site erythema	1124	1.54
General disorders and administration site conditions	Injection site swelling	921	1.26
Nervous system disorders	Hypotonia	617	0.85
Vascular disorders	Pallor	558	0.77
Skin and subcutaneous tissue disorders	Erythema	546	0.75
General disorders and administration site conditions	Injection site induration	480	0.66
Skin and subcutaneous tissue disorders	Urticaria	471	0.65
Skin and subcutaneous tissue disorders	Rash	468	0.64

1. Including regulatory non-serious and consumer reports, but excluding clinical trial cases.

All these events were reported with a frequency between 0.64 to 5.77 per 100 000 doses distributed.

Since the last PSUR the top 10 events has not significantly changed in the reporting frequency except for 'Inappropriate schedule of drug administration', which is no longer part of the top 10 events. Conversely, Urticaria and Rash, which are already quoted in the GDS/RSI, appear with a relative reportive frequency of 0.65 per 100 000 doses distributed.

9.2. Summary of Evaluations

No new safety signals were identified and/or evaluated during the reporting period.

9.3. Adverse events of interest

The cumulative count of an event since launch is provided in the following sections is based on the count of MedDRA PTs from cases originating from spontaneous reporting (including non-medically verified and regulatory non-serious cases).

9.3.1. Cases with a fatal outcome

During the period covered by this report 13 fatal cases were identified.

Ten cases suggestive of sudden deaths (sudden infant death syndrome: SIDS and sudden unexpected death in infancy: SUDI) were identified during the period covered by this PSUR. Cases remained poorly documented in the following suspected SUDI (B0706503A, B0727175A, and B0735723A) or without rationale explanation other than otitis media (D0071496A). SIDS was assessed in all other cases and autopsy confirmed the absence of causes (D0072663A, B0688734A, B0705290A, B0716780A, and D0070324A). A possible circulatory or septic shock was assessed for the last case but autopsy is still expected (D0072852A).

Death occurred in a context of Viral Meningitis (B0683335A); during multi organ failure contemporary of acute meningitis (possible pneumococcus) (B0700040A), death in a context of severe hypoxic-ischemic encephalopathy (B0712016A).

As shown in [Table 34](#), 74 cases suggestive of sudden deaths have been received since launch, corresponding to a reporting frequency of 0.10 per 100 000 doses distributed (frequency of 0.08 per 100,000 doses distributed over the last one-year period).

Table 34 Reporting rate of sudden death since launch per PSUR period

PSUR #	Period	Time period	Number of doses sold doses	Number of SD as reported in the different PSURs	reporting rate per 100,000 doses distributed
16	23oct10-22oct11	1Y	12301693	10	0.08
15	23oct09-22oct10	1Y	11981722	10	0.08
14	23oct08-22oct09	1Y	11496552	11	0.09
13	23oct07-22oct08	1Y	10067611	7	0.07
12	23oct06-22oct07	1Y	8621066	6	0.07
11	23oct05-22oct06	1Y	7166964	9	0.13
10	23apr05-22oct05	6M	2282686	2	0.09
9	23oct00-22apr05	4 1/2Y	9681894	18	0.19
8	23apr04-22oct04	6M	1386298	1	0.07
7	23oct03-22apr04	6M	1246906	5	0.40
6	23apr03-22oct03	6M	1247422	4	0.32
5	23oct02-22apr03	6M	1041975	1	0.10
4	23apr02-22oct02	6M	998814	0	0.00
3	23oct01-22apr02	6M	772137	1	0.13
2	23apr01-22oct01	6M	1050000	1	0.10
1	23oct00-22apr01	6M	430000	0	0.00

A cumulative review of Sudden Death since launch has been performed. Follow-up information was taken into account.

9.3.1.1. Cases of Sudden death

9.3.1.1.1. Introduction

In the assessment report (dated 3 March 2010) of PSUR 14, EMA request that “*The MAH should try to collect relevant and recent data of background incidence rates of sudden death in other European countries. An observed/expected analysis of sudden death should be performed in the next PSUR as well.*”

9.3.1.1.2. Methods

• Literature search

In order to collect relevant and recent data, a literature review of sudden infant death was performed for Europe. The search of the literature was made in PubMed and Embase using simultaneously the key words “sudden infant death” or “sudden death”, “incidence rate” and “Europe”; only publications after 1990 were selected due to the effect of the “Back to Sleep” campaign performed in several European countries. Publications were limited to those published in French and English languages. The bibliographies of identified studies and reviews were searched to identify additional studies of interest. The German Federal Statistical Office was also consulted on line.

- **Observed to Expected Analysis**

To estimate the expected numbers, the incidence rate of SID was considered homogenous within each age (i.e. over 1st or 2d year of life); therefore the expected number over any day was linearly extrapolated (i.e. 1/365) from the prevalence per birth cohort. The number of cases expected to occur within a predetermined risk period following vaccination (Ne) for children under 1 year of age and those between 1 and 2 years of age is derived from the following formula:

$$Ne = Inc \times Nbc \times RiskPeriod \times \alpha$$

where

Inc = the incidence of the disease in the first or second year of life

0.454 per 1,000 live births for < 1 year olds

0.062 per 1,000 live births for 1 < 2 year olds

Nbc = the number of doses of vaccine sold since launch (assumption: proportion of adverse events by age is representative for the actual age distribution at vaccination).

$Risk\ Period$ = adjustment from a predetermined risk period (Days/365)

α = healthy vaccinee correction factor (taken here to be 0.8 based on various case-control studies of SIDS or SUID).

9.3.1.1.3. Results

[Table 35](#) present the background incidence rate of Sudden Infant Death in Europe from the selected publications.

Table 35 Incidence rate of Sudden Infant Death (<1 year of age) per 1,000 live births

Country/Population	Time period	Incidence Rate (/1 000 live birth)	Source
Data from the European Concerted Action on Sids. Case-control studies of SIDS done in 20 regions in Europe.	1992-1996	European range: 0.17 – 1.3 (median: 0.6)	Carpenter, 2004
Ireland. Data from National Sudden Infant Death Register.	1993-1997	0.80	Mehanni, 2000
Austria. Prospective study. Data from autopsy records in the Tyrol.	1994-1998	0.4	Kiechl-Kohlendorfer, 2001
Italy. Data from mortality registry of the 15 health districts in the Lombardy region.	1990-2000	0.13-0.54	Montomoli, 2004

- Observed/Expected Analysis of Sudden Deaths (SD)**

Given the attention that has been given to the occurrence of sudden deaths in children in the second year of life within 14 days of the administration of hexavalent vaccines, the Company evaluated whether the number of sudden deaths reported in this age group exceeded the number one could expect to occur by coincidence, i.e. from the natural background incidence of sudden deaths.

Since the distribution of the age at which subjects are vaccinated is unknown, the Company assumed that the proportion of adverse events by age is representative for the actual age distribution at vaccination. It can thus be estimated that 75% of all recipients of Infanrix hexa were in their first year of life, and 20% were in their second year of life (5% were not attributable because the age at vaccination was unknown). Therefore the number of doses (since launch) was estimated to be 54,7 and 14,6 millions respectively. Given that Germany is the main country where Infanrix hexa doses are distributed (close to 30% only in Germany), it was assumed that the incidence of sudden death observed in Germany is representative for the entire population of Infanrix hexa recipients (German Federal Bureau of Statistics, Statistisches Bundesamt; incidence rate in 1st year of life: 0.454/1,000 live births; second year: 0.062/1,000 live births, data 2008). These rates are in line with the other rates described above. A healthy vaccinee correction factor (taken here to be 0.8 based on various case-control studies of SIDS or SUID) was applied. The results of this analysis are present in [Table 36](#) which shows the number of sudden deaths that could be expected to occur by chance within a range of days post vaccination.

Table 36 Cumulative number of observed and expected cases of SD following Infanrix hexa in children in their first or second year of life

Time since vaccination (days)	Observed (1st year)	Expected	Observed (2d year)	Expected
0	16	54.4	2	1.98
1	29	108.8	5	3.96
2	42	163.2	6	5.94
3	50	217.6	6	7.92
4	57	272	6	9.9
5	60	326.4	7	11.88
6	60	380.8	7	13.86
7	62	435.2	7	15.84
8	63	489.6	7	17.82
9	65	544	7	19.8
10	65	598.4	7	21.78
11	65	652.8	7	23.76
12	65	707.2	7	25.74
13	65	761.6	8	27.72
14	65	816	8	29.7
15	66	870.4	8	31.68
16	67	924.8	8	33.66
17	67	979.2	8	35.64
18	67	1033.6	8	37.62
19	67	1088	8	39.6

This analysis shows that the number of sudden death cases reported after vaccination with Infanrix hexa is below the number of cases expected in children in their 1st year of life; it is equal or below the number of cases expected in children between in their 2d year of life.

The Company monitors these cases and their reporting frequencies on an ongoing basis.

9.3.1.1.4. Limitations

There are several limitations for Observed/Expected analyses, and several levels of uncertainty. The major factors affecting O/E analyses are related to:

- Underreporting, reporting biases, and incomplete case details.
- Uncertainty on the number of subjects actually vaccinated.
- No age stratification within the two age groups.

9.3.2. Other adverse events of interest

9.3.2.1. Blood and lymphatic system disorders

9.3.2.1.1. *Anaemia haemolytic autoimmune, Haemolytic anemia and Haemorrhagic diathesis*

One (1) case of Anaemia haemolytic autoimmune, no (0) case of Haemolytic anaemia and two (2) cases of Haemorrhagic diathesis were reported during the period (see Section 6.5.2.1).

D0072751A described a 7-month-old male subject who experienced anemia haemolytic autoimmune within 28 days of Infanrix hexa vaccination. B0737478A described a 4-month-old male subject who experienced haemorrhagic diathesis 8 hours after second dose of Infanrix hexa and first dose of Prevenar. D0070397A described a 3-month-old male subject who experienced haemorrhagic diathesis in the context of an upper respiratory tract infection within 24 hours of receiving the first dose of Infanrix hexa, Prevenar and Rotarix.

These three cases represent a reporting frequency of **0.02** cases per 100 000 doses distributed during the period. Since launch, 10 spontaneous cases of Anaemia haemolytic autoimmune/Haemolytic anemia/Haemorrhagic diathesis were received, corresponding to a reporting frequency of **0.01** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal. The Company closely monitors cases of Anaemia haemolytic autoimmune and Haemolytic anemia.

9.3.2.1.2. *Autoimmune thrombocytopenia, Idiopathic thrombocytopenic purpura, Thrombocytopenic purpura and Thrombocytopenia*

No (0) case of Autoimmune thrombocytopenia, five (5) cases of Idiopathic thrombocytopenic purpura, four (4) cases of Thrombocytopenic purpura and nine (9) cases of Thrombocytopenia were reported during the period (see Section 6.5.2.1). Autoimmune thrombocytopenia was confirmed by positive antiplatelet antibodies in only one case (D0071125A).

These 15 cases represent a reporting frequency of **0.12** cases per 100 000 doses distributed during the period. Since launch, 78 spontaneous cases of Autoimmune thrombocytopenia/Idiopathic thrombocytopenic purpura/Thrombocytopenic purpura, Thrombocytopenia were received, corresponding to a reporting frequency of **0.11** per 100 000 doses distributed.

Thrombocytopenia is a listed event.

The information received with these cases does not provide evidence of a specific safety signal. The Company closely monitors Autoimmune thrombocytopenia, Idiopathic thrombocytopenic purpura, Thrombocytopenic purpura and Thrombocytopenia.

9.3.2.1.3. Thrombocytosis

Two (2) cases of Thrombocytosis were reported during the period (see Section 6.5.2.1.8). Out of these, one was associated with a pemphigoid (B0729166A). It remains difficult to determine a causal relationship between vaccination and the bullous pemphigoid.

These 2 cases represent a reporting frequency of **0.02** cases per 100 000 doses distributed during the period. Since launch, 10 spontaneous cases of Thrombocytosis were received, corresponding to a reporting frequency of **0.01** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.2. Cardiac disorders

9.3.2.2.1. Bradycardia

Eleven (11) cases including the event Bradycardia were reported over the period (see Section 6.5.2.2.1).

These 11 cases represent a reporting frequency of **0.09** cases per 100 000 doses distributed during the period. Since launch, 44 spontaneous cases of Bradycardia were received, corresponding to a reporting frequency of **0.06** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.2.2. Cardiac arrest

Three (3) cases including the PT Cardiac arrest were reported during the period (see Section 6.5.2.2.2). Cases B0706503A and B0716780A are discussed in Section 9.3.1 Cases with a fatal outcome. Case D0069341A described a 3-month-old female who experienced an unspecified collapse less than 1 hour after Infanrix hexa vaccination. Possible epilepsy was suspected without conclusive investigations.

These 3 cases represent a reporting frequency of **0.02** cases per 100 000 doses distributed during the period. Since launch, 11 spontaneous cases of Cardiac arrest were received, corresponding to a reporting frequency of **0.02** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.2.3. Cardio-respiratory arrest

One (1) case including the PT Cardio-respiratory arrest was received during the period (B0705290A) and is discussed in Section 9.3.1 Cases with a fatal outcome.

9.3.2.2.4. Cardiogenic shock

One (1) case including the PT Cardiogenic shock was reported during the period (see Section 6.5.2.2.4) and described a 3-month-old male who experienced cardiogenic shock 12 days after Infanrix hexa vaccination combined with Rotarix and Prevenar. Diagnosis of pre-existing focal atrial tachycardia and heart insufficiency recovered with anti-arritmica.

This case represents a reporting frequency of **0.01** cases per 100 000 doses distributed during the period. It is the first spontaneous case of Cardiogenic shock since launch.

The information received with this case does not provide evidence of a specific safety signal.

9.3.2.2.5. Cyanosis

Fifty eight (58) cases including the preferred term Cyanosis were identified during the period (see Section 6.5.2.2.5). Most were reported in association with a concurrent causal disease.

These 58 cases represent a reporting frequency of **0.47** cases per 100 000 doses distributed during the period. Since launch, 284 spontaneous cases of Cyanosis were received, corresponding to a reporting frequency of **0.39** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal. The Company closely monitors Cyanosis.

9.3.2.3. Eye disorders

9.3.2.3.1. Gaze palsy

Eighteen (18) cases including the event Gaze palsy were identified during the period. In two-third of cases the event was associated to a reported convulsion. The outcomes resolved spontaneously in half of the cases.

These 18 cases represent a reporting frequency of **0.18** cases per 100 000 doses distributed during the period. Since launch, 70 spontaneous cases of Gaze palsy were received, corresponding to a reporting frequency of **0.10** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.4. Gastrointestinal disorders

9.3.2.4.1. Diarrhoea haemorrhagic, Haematochezia, Intussusception, Rectal haemorrhage

Six (6) cases of Diarrhoea haemorrhagic/Haematochezia/Intussusception/Rectal haemorrhage were identified during the period (see Section 6.5.2.4).

These 6 cases represent a reporting frequency of **0.05** cases per 100 000 doses distributed during the period. Since launch, 41 spontaneous cases of Diarrhoea haemorrhagic/Haematochezia/Intussusception/Rectal haemorrhage were received, corresponding to a reporting frequency of **0.06** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal. The Company closely monitors cases of Haematochezia.

9.3.2.5. General disorders and administration site conditions

9.3.2.5.1. Abscess sterile, Injection site abscess sterile

Seven (7) cases of Abscess sterile/Injection site abscess sterile were received during the period (see Section [6.5.2.5.1](#)).

These 7 cases represent a reporting frequency of **0.06** cases per 100 000 doses distributed during the period. Since launch, 38 spontaneous cases of Abscess sterile/Injection site abscess sterile were received, corresponding to a reporting frequency of **0.05** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.5.2. Extensive swelling of vaccinated limb

Twenty-eight (28) cases of Extensive swelling of vaccinated limb (see Section [6.5.2.5.2](#)), out of which 5 were quoted as serious, were received during the period. The reported outcomes resolved in 80% of cases and improved in the others.

These 28 cases represent a reporting frequency of **0.23** cases per 100 000 doses distributed during the period. Since launch, 65 spontaneous cases of Extensive swelling of vaccinated limb were received, corresponding to a reporting frequency of **0.09** per 100 000 doses distributed.

Extensive swelling reactions and swelling of the entire vaccinated limb is included in the current Reference Safety Information of Infanrix hexa. The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.5.3. Gait disturbance

During the period, 19 cases of Gait disturbance were received (see Section [6.5.2.5.3](#)). Out of these, 18 cases were associated with at least one other class event (pyrexia and/or nervous system). The outcome was resolved in 75% of the serious cases.

These 19 cases represent a reporting frequency of **0.15** cases per 100 000 doses distributed during the period. Since launch, 71 spontaneous cases of Gait disturbance were received, corresponding to a reporting frequency of **0.10** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.5.4. Injection site urticaria

See Section 9.3.2.11.5 Urticaria, Urticaria popular and Urticaria thermal.

9.3.2.5.5. Nodule, Injection site nodule and Subcutaneous nodule

Twenty seven (27) cases of Nodule/Injection site nodule/Subcutaneous nodule were received during the period (see Sections 6.5.2.5.4, 6.5.2.5.6 and 6.5.2.11.6).

These 26 cases represent a reporting frequency of **0.21** cases per 100 000 doses distributed during the period. Since launch, 178 spontaneous cases of Nodule/Injection site nodule/Subcutaneous nodule were received, corresponding to a reporting frequency of **0.24** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal. The Company closely monitors Injection site nodule.

9.3.2.6. Immune system disorders

9.3.2.6.1. Anaphylactic shock, Anaphylactic reaction, Anaphylactoid reaction and Drug hypersensitivity

Seven (7) cases of Anaphylactic shock/Anaphylactic reaction/Anaphylactoid reaction/Drug hypersensitivity were received during the period (see Section 6.5.2.6).

The individual reports were reviewed following the case definition and diagnostic levels of certainty developed by The Brighton Collaboration Anaphylaxis Working Group. Three (3) cases of Anaphylactic shock were reported over the period. B0680987A and B0741646A were classified as Level 2 and 3 of diagnostic certainty, respectively. Case D0071107A was classified as Level 4 of diagnostic certainty.

Four (4) additional cases of anaphylactic reaction and hypersensitivity were reported over the period. B0698663A was classified as Level 2 and D0072050A as Level 5 of diagnostic certainty. In case D0072500A, the subject did not experience anaphylaxis (Level 5 of diagnostic certainty). The case was also received as pharmaceutical product complaint and it was concluded that there was no evidence for a specific safety signal for the used lot of Infanrix hexa. Case B0712429A was a generalised allergic reaction (exanthema) where a Salmonella sepsis could have played a trigger role in drug hypersensitivity (Level 5 of diagnostic certainty).

The 4 cases that were Level 2, 3 or 4 represent a reporting frequency of **0.03** cases per 100 000 doses distributed during the period. Since launch, 29 spontaneous cases of Anaphylactic shock/ Anaphylactic reaction/Anaphylactoid reaction/Drug hypersensitivity were received (regardless of Brighton certainty level), corresponding to a reporting frequency of **0.04** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal. The Company closely monitors allergic reactions (including Anaphylactic reaction and Anaphylactoid reaction).

9.3.2.7. Infections and infestations

9.3.2.7.1. Abscess, Abscess limb, Incision site abscess, Injection site abscess, Injection site infection, Streptococcal abscess

During the reporting period, 25 cases were received including one of the following MedDRA Preferred Terms: Abscess (n=10), Abscess limb (n=1), Incision site abscess (n=2), Injection site abscess (n=12), Injection site infection (n=2), Streptococcal abscess (n=2) (see Section 6.5.2.7.1). There was no clustering of these cases by batch, supportive of a manufacturing issue.

These 25 cases represent a reporting frequency of **0.20** cases per 100 000 doses distributed during the period. Since launch, 144 spontaneous cases of Abscess/Abscess limb/Incision site abscess/Injection site abscess/Injection site infection/Streptococcal abscess were received, corresponding to a reporting frequency of **0.20** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal. The Company closely monitors Abscess and Injection site abscess.

9.3.2.7.2. Cellulitis and Injection site cellulitis

Four (4) cases of Cellulitis/Injection site cellulitis were received during the period (see Sections 6.5.2.7.2 and 6.5.2.7.4).

These 4 cases represent a reporting frequency of **0.03** cases per 100 000 doses distributed during the period. Since launch, 39 spontaneous cases of Cellulitis/Injection site cellulitis were received, corresponding to a reporting frequency of **0.05** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.7.3. Encephalic infection

See Section 9.3.2.9.5 Encephalitis, Encephalopathy and Encephalic infection.

9.3.2.7.4. Meningitis aseptic, Meningitis pneumococcal, Meningitis viral

Four (4) cases of Meningitis aseptic/Meningitis pneumococcal/Meningitis viral were received during the period (see Sections 6.5.2.7.5, 6.5.2.7.6 and 6.5.2.7.7).

These 4 cases represent a reporting frequency of **0.03** cases per 100 000 doses distributed during the period. Since launch, 12 spontaneous cases of Meningitis aseptic/Meningitis pneumococcal/Meningitis viral were received, corresponding to a reporting frequency of **0.02** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.7.5. Osteomyelitis

One (1) case (D0069814A) diagnosed with Osteomyelitis at tibia metaphysis left medial with periosteal abscess (bone abscess) and treated surgically was received during the period (see Section [6.5.2.7.8](#)).

This case represents a reporting frequency of **0.01** cases per 100 000 doses distributed during the period. Since launch, 4 spontaneous cases of Osteomyelitis were received, corresponding to a reporting frequency of **0.01** per 100 000 doses distributed.

The information received with this case does not provide evidence of a specific safety signal.

9.3.2.7.6. Pneumococcal sepsis, Salmonella sepsis, Sepsis, Septic shock

Six (6) cases of Pneumococcal sepsis/Salmonella sepsis/Sepsis/Septic shock were received during the period (see Sections [6.5.2.7.9](#), [6.5.2.7.10](#), [6.5.2.7.11](#) and [6.5.2.7.12](#)).

These 6 cases represent a reporting frequency of **0.05** cases per 100 000 doses distributed during the period. Since launch, 35 spontaneous cases of Pneumococcal sepsis/Salmonella sepsis/Sepsis/Septic shock were received, corresponding to a reporting frequency of **0.05** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.8. Musculoskeletal and connective tissue disorders

9.3.2.8.1. Muscle spasms

Seventeen (17) cases of Muscle spasms were reported during the period (see Section [6.5.2.8.1](#)). These were associated with other neurologic signs such as convulsion (n=8).

These 17 cases represent a reporting frequency of **0.14** cases per 100 000 doses distributed during the period. Since launch, 53 spontaneous cases of Muscle spasms were received, corresponding to a reporting frequency of **0.07** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.8.2. Soft tissue necrosis

One (1) case of Soft tissue necrosis was reported during the period (see Section [6.5.2.8.2](#)).

This case represents a reporting frequency of **0.01** cases per 100 000 doses distributed during the period. This is the second Soft tissue necrosis case received since launch.

The information received with this case does not provide evidence of a specific safety signal.

9.3.2.9. Nervous system disorders

9.3.2.9.1. Cerebral atrophy and Cerebral ischemia

Three (3) cases of Cerebral atrophy/Cerebral ischemia were reported during the period (see Section 6.5.2.9.1). Case B0716780A (Cerebral atrophy) is discussed in Section 9.3.1.1 Cases of Sudden death. Death occurred through multi organ failure.

These 3 cases represent a reporting frequency of **0.02** cases per 100 000 doses distributed during the period. Since launch, 11 spontaneous cases of Cerebral atrophy/Cerebral ischemia were received, corresponding to a reporting frequency of **0.02** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.9.2. Seizures and Epilepsy

During the period, 118 cases of Clonic convulsion/Clonus/Convulsion/Febrile convulsion/Grand mal convulsion/Myoclonus/Partial seizures/Seizure like phenomena/Tonic clonic movements/Tonic convulsion were received, as well as, 19 cases of Complex partial seizures/Epilepsy/Infantile spasms/Petit Mal Epilepsy/Status epilepticus (see Section 6.5.2.9.2).

These 118 and 19 cases represent a reporting frequency of **0.96** and **0.15** cases per 100 000 doses distributed during the period, respectively. Since launch, 761 spontaneous cases of Convulsions (any kind of convulsion) were received, corresponding to a reporting frequency of **1.04** per 100 000 doses distributed.

Convulsions (with or without fever) is included in the current Core Safety Information for Infanrix hexa.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.9.3. Demyelination and Demyelinating polyneuropathy

Two (2) cases of Demyelination/Demyelinating polyneuropathy were received during the period (see Section 6.5.2.9.3).

These 2 cases represent a reporting frequency of **0.02** cases per 100 000 doses distributed during the period. Since launch, 6 spontaneous cases of Demyelination/Demyelinating polyneuropathy were received, corresponding to a reporting frequency of **0.01** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.9.4. Depressed level of consciousness and Loss of consciousness

Fifty four (54) cases of Depressed level of consciousness/Loss of consciousness were reported during the period (see Section 6.5.2.9.4).

These 54 cases represent a reporting frequency of **0.44** cases per 100 000 doses distributed during the period. Since launch, 280 spontaneous cases of Depressed level of consciousness/Loss of consciousness were received, corresponding to a reporting frequency of **0.38** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.9.5. Encephalitis, Encephalopathy and Encephalic infection

Five (5) cases of Encephalitis/Encephalopathy/Encephalic infection were received during the period (see Section 6.5.2.9.5). Postvaccinal cerebellitis was compatible with the time sequence (D0070015A). A causal relationship between Infanrix hexa and Prevenar was reported but the relationship remained dubious in two other cases (D0071549A, B0692285A). Case B0686208A lacked data on subject medical and results of investigation.

These 5 cases represent a reporting frequency of **0.04** cases per 100 000 doses distributed during the period. Since launch, 34 spontaneous cases of Encephalitis/Encephalopathy/Encephalic infection were received, corresponding to a reporting frequency of **0.05** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal. The company closely monitors important neurological events (including Encephalitis and Encephalopathy).

9.3.2.9.6. Guillain-Barre syndrome

Two (2) cases of Guillain-Barré syndrome were reported over the period from Italy (1) and Germany (1) (see Section 6.5.2.9.6). The individual reports were reviewed following the case definition and diagnostic levels of certainty developed by The Brighton Collaboration Guillain-Barré Syndrome Working Group (Sejvar, 2011). The reports were classified to Level 4 of diagnostic certainty as the information provided was insufficient to meet the case definition of GBS according to Brighton Collaboration criteria.

These 2 cases represent a reporting frequency of **0.02** cases per 100 000 doses distributed during the period. Since launch, 5 spontaneous cases of Guillain-Barré syndrome were received, corresponding to a reporting frequency of **0.01** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.9.7. Hemiparesis

One (1) case of Hemiparesis was received during the period (see Section 6.5.2.9.7) and is discussed in Section 9.3.2.9.11 Thalamus haemorrhage.

9.3.2.9.8. Lennox Gastaut syndrome

One (1) case of Lennox-Gastaut syndrome was received during the period (see Section 6.5.2.9.5 Encephalitis, Encephalopathy and Encephalic infection).

This case represents a reporting frequency of 0.01 cases per 100 000 doses distributed during the period. This is the first Lennox-Gastaut syndrome case received since launch.

The information received with this case does not provide evidence of a specific safety signal.

9.3.2.9.9. Somnolence

Over the period 59 cases of Somnolence were reported, out of which 19 were non-serious (see Section 6.5.2.9.10).

These 59 cases represent a reporting frequency of **0.48** cases per 100 000 doses distributed during the period. Since launch, 288 spontaneous cases of Somnolence were received, corresponding to a reporting frequency of **0.39** per 100 000 doses distributed.

Figure 1 shows the yearly reporting rate since launch. Note that the number of Somnolence cases displayed for 2011 differs from the one in this PSUR (i.e. 39 cases in Figure 1 and 59 cases in this PSUR) for the following reasons:

- The reporting rate in Figure 1 is plotted by calendar year and not by PSUR period
- Vaccination date was not provided for all somnolence cases.
- The date used to plot each case is the vaccination date, not the date at which the case was received by GSK Biologicals Clinical Safety and Pharmacovigilance department

The rationale for having chosen to plot the vaccination date instead of the reporting date is that many of these cases were reported with a delay of approximately 100 days after event onset, which contributed to the increase in the reporting rate observed during this period.

Figure 1 Reporting rate of Somnolence cases per 100 000 doses distributed and per calendar year

The information received with these cases, as well as the data in [Figure 1](#), do not provide evidence of a specific safety signal.

9.3.2.9.10. Syncope and Presyncope

Fifteen (15) cases of Syncope/Presyncope were received during the period (see Section [6.5.2.9.11](#)).

These 15 cases represent a reporting frequency of **0.12** cases per 100 000 doses distributed during the period. Since launch, 68 spontaneous cases of Syncope/Presyncope were received, corresponding to a reporting frequency of **0.09** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.9.11. Thalamus haemorrhage

One (1) case of Thalamus haemorrhage was received during the period (see Section [6.5.2.9.12](#)).

This case represents a reporting frequency of 0.01 cases per 100 000 doses distributed during the period. This is the first Thalamus haemorrhage case received since launch.

The information received with this case does not provide evidence of a specific safety signal.

9.3.2.9.12. VIth nerve paralysis and VIIth nerve paralysis

Three (3) cases of VIth nerve paralysis/VIIth nerve paralysis were received during the period (see Sections [6.5.2.9.13](#) and [6.5.2.9.14](#)).

These 3 cases represent a reporting frequency of **0.12** cases per 100 000 doses distributed during the period. Since launch, 7 spontaneous cases of VIth nerve paralysis/VIIth nerve paralysis were received, corresponding to a reporting frequency of **0.01** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.10. Respiratory, thoracic and mediastinal disorders

9.3.2.10.1. Apparent life threatening event

Four (4) cases of Apparent life threatening event were received during the period (see Section [6.5.2.10.1](#)).

These 4 cases represent a reporting frequency of **0.03** cases per 100 000 doses distributed during the period. Since launch, 33 spontaneous cases of Apparent life threatening event were received, corresponding to a reporting frequency of **0.05** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.10.2. Asphyxia

One (1) case of Asphyxia was reported during the period (see Section [6.5.2.10.2](#)) and is discussed in Section [9.3.1](#) Cases with a fatal outcome.

9.3.2.10.3. Respiratory arrest

Seven (7) cases of Respiratory arrest were received during the period (see Section [6.5.2.10.3](#)).

These 7 cases represent a reporting frequency of **0.06** cases per 100 000 doses distributed during the period. Since launch, 36 spontaneous cases of Respiratory arrest were received, corresponding to a reporting frequency of **0.05** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.11. Skin and subcutaneous tissue disorders

9.3.2.11.1. Angioedema

Four (4) cases of Angioedema were reported over the period (see Section [6.5.2.11.1](#)). All cases lacked data on the subject's medical history and other possible diagnosis to provide a precise overall assessment.

These 4 cases represent a reporting frequency of **0.03** cases per 100 000 doses distributed during the period. Since launch, 34 spontaneous cases of Angioedema were received, corresponding to a reporting frequency of **0.05** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.11.2. Erythema multiforme

Two (2) cases of Erythema multiforme were reported during the period (see Section [6.5.2.11.2](#)).

These 2 cases represent a reporting frequency of **0.02** cases per 100 000 doses distributed during the period. Since launch, 15 spontaneous cases of Erythema multiforme were received, corresponding to a reporting frequency of **0.02** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.11.3. Henoch Schonlein Purpura and Purpura

Five (5) cases of Henoch-Schonlein purpura/Purpura were received during the period (see Sections [6.5.2.11.3](#) and [6.5.2.11.5](#)).

These 5 cases represent a reporting frequency of **0.04** cases per 100 000 doses distributed during the period. Since launch, 38 spontaneous cases of Henoch-Schonlein purpura/Purpura were received, corresponding to a reporting frequency of **0.05** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal. The Company closely monitors cases of Purpura and Henoch-Schonlein purpura.

9.3.2.11.4. Petechiae

Twenty nine (29) cases of Petechiae were reported during the period (see Section [6.5.2.11.4](#)). In the majority of serious cases, haematologic disorders were associated: idiopathic / non-specified thrombocytic purpura or thrombocytopenia.

These 29 cases represent a reporting frequency of **0.24** cases per 100 000 doses distributed during the period. Since launch, 161 spontaneous cases of Petechiae were received, corresponding to a reporting frequency of **0.22** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal. The Company closely monitors cases of Petechiae.

9.3.2.11.5. *Urticaria, Urticaria papular and Urticaria thermal*

Sixty seven (67) cases of Urticaria/Urticaria papular/Urticaria thermal were received during the period (plus one received during a previous period but not included in a previous PSUR), out of which most resolved spontaneously (see Section 6.5.2.11.7).

These 68 cases represent a reporting frequency of **0.55** cases per 100 000 doses distributed during the period. Since launch, 432 spontaneous cases of Urticaria/Urticaria papular/Urticaria thermal were received, corresponding to a reporting frequency of **0.59** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.11.6. *Subcutaneous nodule*

Discussed in Section 9.3.2.5.5 Nodule, Injection site nodule and Subcutaneous nodule.

9.3.2.12. Vascular disorders

9.3.2.12.1. *Circulatory collapse*

Seven (7) cases of Circulatory collapse were received during the period (see Section 6.5.2.12.1).

These 7 cases represent a reporting frequency of **0.06** cases per 100 000 doses distributed during the period. Since launch, 38 spontaneous cases of Circulatory collapse were received, corresponding to a reporting frequency of **0.05** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal.

9.3.2.12.2. *Kawasaki's disease*

Three (3) cases of Kawasaki's disease were reported during the period (see Section 6.5.2.12.2). In 2 out of these 3 cases, the reported information is compatible with the typical symptomatology of Kawasaki's disease and subjects were treated with immunoglobulins. One of the subjects developed pericarditis. The etiology of Kawasaki's disease remains unknown although in 2 of the cases the clinical history suggests an infectious disease.

These 3 cases represent a reporting frequency of **0.02** cases per 100 000 doses distributed during the period. Since launch, 21 spontaneous cases of Kawasaki's disease were received, corresponding to a reporting frequency of **0.03** per 100 000 doses distributed.

The information received with these cases does not provide evidence of a specific safety signal. The Company closely monitors cases of Kawasaki's disease.

9.4. Areas of Regulatory Interest

Areas of regulatory interest (specifically Drug Interactions, Overdose and Medication Errors, Abuse Potential, Pregnancy and Lactation, Use in Children) routinely monitored throughout the product lifecycle and during the period of the PSUR are presented below. Note that non-medically verified reports and non-serious reports received from regulatory authorities are included in these analyses.

9.4.1. Drug interactions

No cases of potential drug interactions have been received during the period.

Most spontaneous cases reported during the period included coadministration(s) with other vaccines (mostly pneumococcal vaccines). Vaccination with pneumococcal vaccines is standard practice in the countries where most reports originated from (Germany and Italy).

No relevant findings were noticed as regarding the co-administration profile of the vaccine. No cluster of events suggestive of potential interaction was found.

No new important safety information regarding drug interactions has been identified in the time period.

9.4.2. Overdose and Medication Errors

There were 319 cases of potential overdose and/or reports of medication error have been received during the reporting period. Non-medically verified and regulatory non-serious cases are included in this analysis.

In addition to cases of overdoses, an inappropriate drug use event has been reported 249 times over the period. An overview per category of maladministration is presented in the below table. Note that a case can contain more than one PT related to maladministration.

In view of the varying ways in which reports of overdose and medication error are described and coded, there is often much overlap between these concepts.

9.4.2.1. Overdose

“Overdose” is defined as more than the recommended dose of vaccine administered at the same occasion (either two vaccine doses administered too soon one after each other or two vaccines with overlapping components accidentally co-administered.)

A total of 30 Overdose/Accidental overdose cases were received during the period. Out of these 30, adverse events were reported in 8 cases, including two serious. These cases are listed in [Table 37](#).

Table 37 Overdose cases reported with adverse events during the period

Case ID	Seriousness	Events PT Comma Sep
B0683346A	Not serious	Wrong drug administered, Overdose, Somnolence, Irritability
B0685920A	Not serious	Irritability, Overdose, Wrong technique in drug usage process
B0708048A	Not serious	Pyrexia, Overdose, Wrong drug administered
B0736206A	Not serious	Pyrexia, Decreased appetite, Wrong drug administered, Overdose
B0738500A	Serious	Injection site induration, Pyrexia, Wrong technique in drug usage process, Overdose
B0741664A	Not serious	Accidental overdose, Pyrexia
B0743545A	Serious	Injection site reaction, Wrong technique in drug usage process, Medication error, Overdose, Injection site induration, Pyrexia
D0070270A	Not serious	Pyrexia, Restlessness, Accidental overdose

The two serious Overdose cases are described below:

- **Case B0738500A (France): Injection site induration, Pyrexia, Wrong technique in drug usage process, Overdose.**

This case described an inappropriate preparation of medication in a 4-month-old infant who was vaccinated with Infanrix hexa. In August 2011, the subject received a second dose of Infanrix hexa without the Hib component (inappropriate preparation of medication). A third dose of Infanrix hexa was administered immediately (overdose). At an unspecified time after vaccination, the subject presented with mild fever and induration at injection site on 2 cm of diameter.

- **Case B0743545A (France): Injection site reaction, Wrong technique in drug usage process, Medication error, Overdose, Injection site induration, Pyrexia**

This case described the occurrence of local reaction at injection site in a 4-month-old female who was vaccinated with Infanrix hexa. On 09 August 2011 the subject received a first dose of Infanrix hexa. The vaccine used had not been properly reconstituted (wrong injection technique, medication error). As the physician thought he had only administered the solution for reconstitution of the vaccine, the physician administered on that same date an additional dose of reconstituted Infanrix hexa. The subject subsequently received two doses of diphtheria, tetanus-acellular pertussis, hepatitis B vaccine (overdose). Medication error was reported. One day after the vaccination, the subject experienced induration at injection site of 2 cm which lasted 8 days and mild febricula during 24 hours. At the time of reporting, the events were resolved without sequelae.

The information received with these cases does not provide evidence of a specific safety signal.

9.4.2.2. Medication Errors

In addition to Overdose and Accidental overdose cases, 301 cases involving medication errors were received during period. Out of these, 250 were reported with no adverse events and 51 with at least one adverse event. An overview per category of maladministration is presented in [Table 38](#). Note that a case can contain more than one PT related to maladministration.

CONFIDENTIAL

CONFIDENTIAL

Table 38 **Overview of medication errors by category of maladministration**

Event PT	Number Of Events
Wrong technique in drug usage process	88
Incorrect product storage	47
Wrong drug administered	30
Inappropriate schedule of drug administration	28
Drug administration error	23
Incorrect dose administered	23
Underdose	20
Incorrect route of drug administration	18
Incorrect storage of drug	18
Off label use	13
Expired drug administered	10
Drug administered to patient of inappropriate age	7
Drug prescribing error	1
Medication error	1
Accidental exposure	1

No new important safety information regarding medication errors has been identified during the time period.

9.4.3. Abuse or misuse

Not applicable to vaccines.

9.4.4. Pregnancy and Lactation**9.4.4.1. Pregnancy**

All cases involving a pregnant patient are included. In addition, the search strategy includes a broad selection of MedDRA PTs suggesting exposure *in utero* or via breast feeding or indicative of birth defects (e.g. congenital or hereditary disorders). Thus the search retrieves cases where pregnancy outcome is abnormal, normal or unknown. Cases involving females over 60 years of age and adult males (where the case was not reported as a partner pregnancy) have been excluded. Note that this search does not include the entire SMQ for 'Adverse Pregnancy Outcome/Reproductive Toxicity (incl neonatal disorders)'; furthermore, it includes some terms that are not in the SMQ.

One (1) case possibly related to administration during pregnancy or lactation was received during the reporting period:

- **B0681410A (France): Maternal exposure during pregnancy, Off label use**

This prospective case of pregnancy was reported by a gynecologist and described a vaccine exposure during pregnancy in a female subject aged between 20 and 29 years old who was vaccinated with Infanrix hexa and meningococcal polysaccharide vaccine group C (Meningitec, non-GSK) during pregnancy (3 weeks of amenorrhea). The subject's medical history included a previous pregnancy with a delivery in July 2010. She had no concurrent pathology and took no concurrent long time treatment. Estimated date of delivery was June 2011. On 30 September 2011 the subject was lost to follow-up. No response to letters. Outcome of pregnancy was unknown.

Pregnancy outcomes for the current reporting period and cumulative totals are summarised in [Table 40](#). Changes in the numbers of the cumulative outcomes since the previous safety update reflect not only the addition of new cases but also follow-up obtained on previously received cases.

Table 40 Pregnancy Outcomes

Outcome	In Period (n)	Cumulative (n)
Live infant, no apparent congenital anomaly ¹	0	1
Live infant with congenital anomaly	0	0
Elective termination, no apparent congenital anomaly ¹	0	0
Elective termination with congenital anomaly	0	0
Spontaneous abortion, no apparent congenital anomaly ¹	0	0
Spontaneous abortion with congenital anomaly	0	0
Stillbirth, no apparent congenital anomaly ¹	0	0
Stillbirth with congenital anomaly	0	0
Ectopic pregnancy	0	0
Molar pregnancy	0	0
Pregnancy ongoing, lost to follow-up or unknown	1	1
Total	1	2

1. Pregnancy outcome categories stating 'no apparent congenital anomaly' include outcomes where it is unknown whether a congenital anomaly occurred.

No new important safety information regarding use in pregnancy has been identified during the time period.

9.4.4.2. Lactation

No cases have been received during the reporting period where Infanrix hexa was given to lactating mothers.

No new important safety information regarding administration during lactation has been identified during the time period.

9.4.5. Special Patient Groups

No new important safety information related to use in children, elderly or organ impaired patients has been identified during the period.

9.4.6. Effects of long-term treatment

Not applicable to vaccines.

9.4.7. Patient/Consumer and other non-healthcare professional reports.

The events of interest described in Section 6.5 within the PSUR review period include all cases (irrespective of source, seriousness and listedness). Non-healthcare professional reports are therefore discussed in Section 6.5 as well. Separate Line Listings and Summary Tabulations are provided as appendices for consumer reports as per guideline E2C(R1).

10. CONCLUSION

From the review of data received during the reporting period and presented in this PSUR, it has been concluded that the safety profile of Infanrix hexa is adequately reflected in the RSI.

There have been no amendments to the Reference Safety Information (RSI) in the current reporting period and no further amendments to the RSI are considered necessary at this time.

The benefit/risk profile of Infanrix hexa continues to be favourable.

The Company will continue to monitor cases of anaemia haemolytic autoimmune, thrombocytopenia, thrombocytopenic purpura, autoimmune thrombocytopenia, idiopathic thrombocytopenic purpura, haemolytic anemia, cyanosis, injection site nodule, abscess and injection site abscess, Kawasaki's disease, important neurological events (including encephalitis and encephalopathy), Henoch-Schonlein purpura, petechiae, purpura, haematochezia, allergic reactions (including anaphylactic and anaphylactoid reactions), cases of lack of effectiveness as well as fatal cases.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated)
and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

GLOBAL DATASHEET

**Combined diphtheria, tetanus, pertussis (acellular), hepatitis B,
poliomyelitis (inactivated) and *Haemophilus influenzae* type b
vaccine**

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
 Version Number: 010
 Version Date: 21 Oct 2010

GLOBAL PRESCRIBER INFORMATION

TITLE

Combined diphtheria-tetanus-acellular pertussis, hepatitis B, enhanced inactivated polio vaccine and *Haemophilus influenzae* type b vaccine.

SCOPE

Trade Name(s)

Infanrix hexa

Formulation and Strength

Powder and suspension for suspension for injection.

1 dose (0.5 ml) contains:

Diphtheria toxoid ¹	not less than 30 International units
Tetanus toxoid ¹	not less than 40 International units
<i>Bordetella pertussis</i> antigens	
Pertussis toxoid ¹	25 micrograms
Filamentous Haemagglutinin ¹	25 micrograms
Pertactin ¹	8 micrograms
Hepatitis B surface antigen ^{2,3}	10 micrograms
Poliovirus (inactivated)	
type 1 (Mahoney strain) ⁴	40 D-antigen unit
type 2 (MEF-1 strain) ⁴	8 D-antigen unit
type 3 (Saukett strain) ⁴	32 D-antigen unit
<i>Haemophilus influenzae</i> type b polysaccharide (polyribosylribitol phosphate) ³	10 micrograms
conjugated to tetanus toxoid as carrier protein	20 - 40 micrograms
¹ adsorbed on aluminium hydroxide, hydrated (Al(OH) ₃)	0.5 milligrams Al ³⁺
² produced in yeast cells (<i>Saccharomyces cerevisiae</i>) by recombinant DNA technology	
³ adsorbed on aluminium phosphate (AlPO ₄)	0.32 milligrams Al ³⁺
⁴ propagated in VERO cells	

The DTPa-HBV-IPV component is presented as a turbid white suspension. Upon storage, a white deposit and clear supernatant can be observed.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

The Hib component is presented as a white powder.

Excipients

It is mandatory for country product information to include both the complete list of excipients for all locally marketed presentations, and any locally imposed excipient warning statements.

Lactose

Sodium chloride (NaCl)

Medium 199 (as stabilizer including amino acids, mineral salts and vitamins)

Water for injections

Residues

Potassium chloride

Disodium phosphate

Monopotassium phosphate

Polysorbate 20 and 80

Glycine

Formaldehyde

Neomycin sulphate

Polymyxin B sulphate

CLINICAL INFORMATION

Indications

Infanrix hexa is indicated for primary and booster vaccination of infants against diphtheria, tetanus, pertussis, hepatitis B, poliomyelitis and *Haemophilus influenzae* type b.

Dosage and Administration

Posology

- **Primary vaccination**

The primary vaccination schedule consists of three doses of 0.5 ml (e.g. 2, 3, 4 months; 3, 4, 5 months; 2, 4, 6 months) or two doses (e.g. 3, 5 months). There should be an interval

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
 Version Number: 010
 Version Date: 21 Oct 2010

of at least 1 month between doses. The Expanded Program on Immunisation schedule (at 6, 10, 14 weeks of age) may only be used if a dose of hepatitis B vaccine has been given at birth.

Locally established immunoprophylactic measures against hepatitis B should be maintained. Where a dose of hepatitis B vaccine is given at birth, Infanrix hexa can be used as a replacement for supplementary doses of hepatitis B vaccine from the age of 6 weeks. If a second dose of hepatitis B vaccine is required before this age, monovalent hepatitis B vaccine should be used.

- **Booster vaccination**

After a vaccination with 2 doses (e.g. 3, 5 months) of Infanrix hexa a booster dose must be given at least 6 months after the last priming dose, preferably between 11 and 13 months of age.

After vaccination with 3 doses (e.g. 2, 3, 4 months; 3, 4, 5 months; 2, 4, 6 months) of Infanrix hexa a booster dose may be given at least 6 months after the last priming dose and preferably before 18 months of age.

Booster doses should be given in accordance with the official recommendations.

Infanrix hexa can be considered for the booster if the composition is in accordance with the official recommendations.

Other combinations of antigens have been studied in clinical trials following primary vaccination with Infanrix hexa and may be used for a booster dose: diphtheria, tetanus, acellular pertussis (DTPa), diphtheria, tetanus, acellular pertussis, *Haemophilus influenzae* type b (DTPa+Hib), diphtheria, tetanus, acellular pertussis, inactivated poliomyelitis, *Haemophilus influenzae* type b (DTPa-IPV+Hib) and diphtheria, tetanus, acellular pertussis, hepatitis B, inactivated poliomyelitis, *Haemophilus influenzae* type b (DTPa-HBV-IPV+Hib).

Method of administration

Infanrix hexa is for deep intramuscular injection.

Contraindications

Hypersensitivity to the active substances or to any of the excipients or residues (see *Formulation and Strength, Excipients and Residues*).

Hypersensitivity after previous administration of diphtheria, tetanus, pertussis, hepatitis B, polio or Hib vaccines.

Infanrix hexa is contraindicated if the child has experienced an encephalopathy of unknown aetiology, occurring within 7 days following previous vaccination with

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

pertussis containing vaccine. In these circumstances pertussis vaccination should be discontinued and the vaccination course should be continued with diphtheria-tetanus, hepatitis B, inactivated polio and Hib vaccines.

Warnings and Precautions

As with other vaccines, administration of Infanrix hexa should be postponed in subjects suffering from acute severe febrile illness. The presence of a minor infection is not a contra-indication.

Vaccination should be preceded by a review of the medical history (especially with regard to previous vaccination and possible occurrence of undesirable events) and a clinical examination.

If any of the following events are known to have occurred in temporal relation to receipt of pertussis-containing vaccine, the decision to give further doses of pertussis-containing vaccines should be carefully considered:

- Temperature of $\geq 40.0^{\circ}\text{C}$ within 48 hours, not due to another identifiable cause.
- Collapse or shock-like state (hypotonic-hyporesponsiveness episode) within 48 hours of vaccination.
- Persistent, inconsolable crying lasting ≥ 3 hours, occurring within 48 hours of vaccination.
- Convulsions with or without fever, occurring within 3 days of vaccination.

There may be circumstances, such as a high incidence of pertussis, when the potential benefits outweigh possible risks.

In children with progressive neurological disorders, including infantile spasms, uncontrolled epilepsy or progressive encephalopathy, it is better to defer pertussis (Pa or Pw) immunization until the condition is corrected or stable. However, the decision to give pertussis vaccine must be made on an individual basis after careful consideration of the risks and benefits.

As with all injectable vaccines, appropriate medical treatment and supervision should always be readily available in case of a rare anaphylactic event following the administration of the vaccine.

Infanrix hexa should be administered with caution to subjects with thrombocytopenia or a bleeding disorder since bleeding may occur following an intramuscular administration to these subjects.

Infanrix hexa should under no circumstances be administered intravascularly or intradermally.

Infanrix hexa contains traces of neomycin and polymyxin. The vaccine should be used with caution in patients with known hypersensitivity to one of these antibiotics.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

Infanrix hexa will not prevent disease caused by pathogens other than *Corynebacterium diphtheriae*, *Clostridium tetani*, *Bordetella pertussis*, hepatitis B virus, poliovirus or *Haemophilus influenzae* type b. However, it can be expected that hepatitis D will be prevented by immunisation as hepatitis D (caused by the delta agent) does not occur in the absence of hepatitis B infection.

A protective immune response may not be elicited in all vaccinees (see *Pharmacodynamic Effects*).

A history of febrile convulsions, a family history of convulsions or Sudden Infant Death Syndrome (SIDS) do not constitute contraindications for the use of Infanrix hexa. Vaccinees with a history of febrile convulsions should be closely followed up as such adverse events may occur within 2 to 3 days post vaccination.

Human Immunodeficiency Virus (HIV) infection is not considered as a contra-indication. The expected immunological response may not be obtained after vaccination of immunosuppressed patients.

Since the Hib capsular polysaccharide antigen is excreted in the urine a positive urine test can be observed within 1-2 weeks following vaccination. Other tests should be performed in order to confirm Hib infection during this period.

Limited data in 169 premature infants indicate that Infanrix hexa can be given to premature children. However, a lower immune response may be observed and the level of clinical protection remains unknown.

The potential risk of apnoea and the need for respiratory monitoring for 48-72h should be considered when administering the primary immunization series to very premature infants (born ≤ 28 weeks of gestation) and particularly for those with a previous history of respiratory immaturity. As the benefit of vaccination is high in this group of infants, vaccination should not be withheld or delayed.

Syncope (fainting) can occur following, or even before, any vaccination as a psychogenic response to the needle injection. It is important that procedures are in place to avoid injury from faints.

Interactions

There are insufficient data with regard to the efficacy and safety of simultaneous administration of Infanrix hexa and Measles-Mumps-Rubella vaccine to allow any recommendation to be made.

Data on concomitant administration of Infanrix hexa with Prevenar (pneumococcal saccharide conjugated vaccine, adsorbed) have shown no clinically relevant interference in the antibody response to each of the individual antigens when given as a 3 dose primary vaccination.

However, high incidence of fever ($> 39.5^{\circ}\text{C}$) was reported in infants receiving Infanrix hexa and Prevenar compared to infants receiving the hexavalent vaccine alone.

Antipyretic treatment should be initiated according to local treatment guidelines.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

As with other vaccines, it may be expected that in patients receiving immunosuppressive therapy, an adequate response may not be achieved.

Pregnancy and Lactation

Pregnancy

As Infanrix hexa is not intended for use in adults, information on the safety of the vaccine when used during pregnancy is not available.

Lactation

As Infanrix hexa is not intended for use in adults, information on the safety of the vaccine when used during lactation is not available.

Ability to perform tasks that require judgement, motor or cognitive skills

Not relevant.

Adverse Reactions

Clinical Trial Data

The safety profile presented below is based on data from more than 16,000 subjects.

As has been observed for DTPa and DTPa-containing combinations, an increase in local reactogenicity and fever was reported after booster vaccination with Infanrix hexa with respect to the primary course.

Adverse reactions reported are listed according to the following frequency:

Very common: $\geq 1/10$
Common: $\geq 1/100$ to $< 1/10$
Uncommon: $\geq 1/1000$ to $< 1/100$
Rare: $\geq 1/10000$ to $< 1/1000$
Very rare: $< 1/10000$

Infections and infestations

Uncommon: upper respiratory tract infection

Metabolism and nutrition disorders

Very common: appetite lost

Psychiatric disorders

CONFIDENTIAL

CONFIDENTIAL

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

Very common: irritability, crying abnormal, restlessness
Common: nervousness

Nervous system disorders

Uncommon: somnolence
Very rare: convulsions (with or without fever)

Respiratory, thoracic and mediastinal disorders

Uncommon: cough*
Rare: bronchitis

Gastrointestinal disorders

Common: vomiting, diarrhoea

Skin and subcutaneous tissue disorders

Common: pruritus*
Rare: rash
Very rare: dermatitis, urticaria*

General disorders and administration site conditions

Very common: pain, redness, local swelling at the injection site (≤ 50 mm), fever $\geq 38^{\circ}\text{C}$, fatigue
Common: local swelling at the injection site (> 50 mm)** , fever $>39.5^{\circ}\text{C}$, injection site reactions, including induration
Uncommon: diffuse swelling of the injected limb, sometimes involving the adjacent joint**

Post Marketing Data

Blood and lymphatic system disorders

Lymphadenopathy, thrombocytopenia

Immune system disorders

Allergic reactions (including anaphylactic and anaphylactoid reactions)

Nervous system disorders

Collapse or shock-like state (hypotonic-hyporesponsiveness episode)

Respiratory, thoracic and mediastinal disorders

Apnoea* [see Warnings and Precautions for apnoea in very premature infants (≤ 28 weeks of gestation)]

Skin and subcutaneous tissue disorders

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

Angioneurotic oedema*

General disorders and administration site conditions

Extensive swelling reactions, swelling of the entire injected limb**, vesicles at the injection site

* observed with other GSK DTPa-containing vaccines

** Children primed with acellular pertussis vaccines are more likely to experience swelling reactions after booster administration in comparison with children primed with whole cell vaccines. These reactions resolve over an average of 4 days.

Experience with hepatitis B vaccine:

Meningitis, mimicking serum sickness, paralysis, encephalitis, encephalopathy, neuropathy, neuritis, hypotension, vasculitis, lichen planus, erythema multiforme, arthritis, muscular weakness have been reported during post-marketing surveillance following GlaxoSmithKline Biologicals' hepatitis B vaccine in infants < 2 years old. The causal relationship to the vaccine has not been established.

Overdosage

Insufficient data are available.

Clinical Pharmacology

† cut-off accepted as indicative of protection

As the immune response to pertussis antigens following Infanrix hexa administration is equivalent to that of Infanrix, the protective efficacy of the two vaccines is expected to be equivalent.

The protective efficacy of the pertussis component of Infanrix against WHO-defined typical pertussis (≥ 21 days of paroxysmal cough) was demonstrated in:

- a prospective blinded household contact study performed in Germany (3, 4, 5 months schedule). Based on data collected from secondary contacts in households where there was an index case with typical pertussis, the protective efficacy of the vaccine was 88.7%.
- a NIH sponsored efficacy study performed in Italy (2, 4, 6 months schedule). The vaccine efficacy was found to be 84%. In a follow-up of the same cohort, the efficacy

CONFIDENTIAL

CONFIDENTIAL

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

was confirmed up to 60 months after completion of primary vaccination without administration of a booster dose of pertussis.

Results of long term follow-up in Sweden demonstrate that acellular pertussis vaccines are highly efficacious in infants when administered according to the 3 and 5 months primary vaccination schedule, with a booster dose administered at approximately 12 months. However, data indicate that protection against pertussis may be waning at 7-8 years of age. This suggests that a second booster dose of pertussis vaccine is warranted in children aged 5-7 years who have previously been vaccinated following this schedule.

Protective immunity against hepatitis B has been shown to persist for at least 3.5 years in more than 90% of children administered four doses of Infanrix hexa. Antibody levels were not different from what was observed in a parallel cohort administered monovalent hepatitis B vaccine.

The effectiveness of the Hib component of Infanrix hexa was investigated via an extensive post-marketing surveillance study conducted in Germany. Over a seven year follow-up period, the effectiveness of the Hib components of two hexavalent vaccines, of which one was Infanrix hexa, was 89.6% for a full primary series and 100% for a full primary series plus booster dose (irrespective of the Hib vaccine used for priming).

Pharmacokinetics

Evaluation of pharmacokinetic properties is not required for vaccines.

Clinical Studies

See *Pharmacodynamic Effects*.

NON-CLINICAL INFORMATION

Preclinical data reveal no special hazard for humans based on conventional studies of safety, specific toxicity, repeated dose toxicity and compatibility of ingredients.

PHARMACEUTICAL INFORMATION

Shelf-Life

The expiry date of the vaccine is indicated on the label and packaging. The expiry date refers to the last day of the month mentioned.

The shelf-life is 3 years.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

Storage

Infanrix hexa should be stored at +2°C to +8°C. Protect from light.

During transport, recommended conditions of storage must be respected.

The DTPa-HBV-IPV suspension and the reconstituted vaccine must not be frozen.

Discard if it has been frozen.

Nature and Contents of Container

The DTPa-HBV-IPV component is presented in a pre-filled syringe or vial.

The Hib component is presented as a white pellet in a glass vial.

The vials and pre-filled syringes are made of neutral glass type I, which conforms to European Pharmacopoeia Requirements.

Vial and pre-filled syringe presentations (with or without needles) are available in packs of 1, 10, 20 and 50.

Vial and vial presentation is available in pack sizes of 1 and 50.

Incompatibilities

Infanrix hexa should not be mixed with other vaccines in the same syringe.

Use and Handling

1. Wording for vial and pre-filled syringe presentation

The DTPa-HBV-IPV suspension should be well shaken in order to obtain a homogeneous turbid white suspension. The DTPa-HBV-IPV suspension and the Hib powder should be inspected visually for any foreign particulate matter and/or variation of physical aspect. In the event of either being observed, discard the vaccine.

Infanrix hexa must be reconstituted by adding the entire content of the pre-filled syringe to the vial containing the Hib powder.

It is good clinical practice to only inject a vaccine when it has reached room temperature. In addition, a vial at room temperature ensures sufficient elasticity of the rubber closure to minimise any coring of rubber particles. To achieve this, the vial should be kept at room temperature (25 ± 3 °C) for at least five minutes before connecting the pre-filled syringe and reconstituting the vaccine.

The reconstituted vaccine presents as a slightly more cloudy suspension than the liquid component alone. This is normal and does not impair the performance of the vaccine. In the event of other variation being observed, discard the vaccine.

After reconstitution, the vaccine should be injected immediately. However the vaccine may be kept for up to 8 hours at room temperature (21°C).

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

Withdraw the entire contents of the vial.

- *Specific instructions for the pre-filled syringe with a luer lock adaptor (PRTC)*

Needle

Syringe

1. Holding the syringe **barrel** in one hand (avoid holding the syringe plunger), unscrew the syringe cap by twisting it anticlockwise.
2. To attach the needle to the syringe, twist the needle clockwise into the syringe until you feel it lock (see picture).
3. Remove the needle protector, which on occasion can be a little stiff.
4. Administer the vaccine.

2. Wording for vial and vial presentation

Upon storage, a white deposit and clear supernatant may be observed in the vial containing the DTPa-HBV-IPV suspension. This does not constitute a sign of deterioration.

Infanrix hexa must be reconstituted by adding the entire content of the vial containing the DTPa-HBV-IPV suspension to the vial containing the Hib powder. To do so, draw up the suspension with a syringe and add the suspension to the powder. The mixture should be well shaken until the powder is completely dissolved in the suspension.

The reconstituted vaccine presents as a slightly more cloudy suspension than the liquid component alone. This is normal and does not impair the performance of the vaccine.

The reconstituted vaccine should be inspected visually for any foreign particulate matter and/or abnormal physical appearance. In the event of either being observed, discard the vaccine.

A new needle should be used to administer the vaccine.

CONFIDENTIAL

CONFIDENTIAL

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated)
and *Haemophilus influenzae* type b vaccine

Version Number: 010

Version Date: 21 Oct 2010

After reconstitution, the vaccine should be used immediately.

Withdraw the entire contents of the vial.

Any unused product or waste material should be disposed of in accordance with local requirements.

N.B. Events are only considered serious if they fulfil GSK medically serious criteria. GSK medically serious criteria are applied automatically only to events from spontaneous, post-marketing or literature case reports. Events arising from Clinical trial cases are not run against the list of GSK medically serious terms. For this reason events may appear as both serious and non-serious. For full explanation see section 6.2.2.

DESCRIBE EVENT(S) Meningitis viral, Convulsion, Yellow skin, Cyanosis, Dehydration, Diarrhoea, Somnolence, Crying, Vomiting, This case was reported by a regulatory authority (NL-College ter Beoordeling van Geneesmiddelen # NL-LRB-111158) and described the occurrence of meningitis in a 2-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-gsk) (Prevenar) for prophylaxis. The subject had no medical history and no concomitant medication. On 13 September 2010 the subject received 1st dose of Infanrix hexa (unknown route, unknown injection site), 1st dose of Prevenar (unknown route, unknown injection site). In September 2010, unspecified time after vaccination with Infanrix hexa and Prevenar, the subject experienced meningitis. 7. & 13. DESCRIBE EVENT(S)

The subject was hospitalised.

On 25 September 2010, 12 days after vaccination with Infanrix hexa and Prevenar, the subject died from meningitis.

It was unknown whether an autopsy was performed. Hospital report was pending.

No further information could be obtained from regulatory authority. Additional data will be sent to us in a proactive way. In the meanwhile, the case has been closed.

Follow up information received on 1 February 2011:

The case has received a second regulatory number : NL-LRB-116469

On 13 September 2010, 3 minutes after vaccination, the subject experienced crying and sleepiness on the same day.

On 18 September 2010, 5 days after vaccination, the subject was found in bed with eyes half-opened and a blue mouth. His skin was yellow/pale. He vomited pink, foaming milk. No fever was observed (37 degrees C).

The boy was hospitalized, diarrhea aggravated and dehydration was diagnosed. Blood test and spinal tap were performed.

The boy had several afebrile convulsions and a MRI showed severe damage of the brain.

No further treatment was given.

On 25 September 2010, 12 days after vaccination, the subject died from viral meningitis.

The regulatory authority considered the events were unlikely to be related with vaccination with Infanrix hexa and Prevenar.

Additional information has been requested but could not be obtained from regulatory authority. The case has therefore been closed.

LABORATORY TEST NAME	TEST DATE	TEST RESULT	LOW NORMAL	HIGH NORMAL
Blood test	Sep2010	unknown		
NMR	Sep2010	brain damage		
Spinal tap	Sep2010	unknown

7. & 13. DESCRIBE EVENT(S)

Prevenar (batch E74711, intramuscular, injection site unknown).
On 10 November 2010, the subject presented with bronchial and nasal congestions, cough, and serous fluid in tympanum (with crying at night) which was diagnosed before the administration of vaccines (medical condition). At 19:00, the subject received her last bottle (250 ml). She went to bed at 19:15 and she was layed in her parent's bed, on a pillow. At 21:45, the father went to bed and found the subject unconscious. Mobile emergency medical unit was contacted which arrived at 22:00. At 22:23 pm, a pediatric mobile emergency medical unit arrived. Resuscitation procedure was started. The subject was intubated and received adrenaline. She was hospitalized and died at 00:00. Tracheal aspiration was positive for klebsiella pneumoniae.

It was unknown whether an autopsy was performed.

Causal relationship of vaccination with Infanrix hexa and Prevenar and sudden infant death was assessed as dubious, according to the French method of imputability.

LABORATORY TEST NAME	TEST DATE	TEST RESULT	LOW NORMAL	HIGH NORMAL
Tracheal aspiration	10Nov2010	positive for kle		

MEDICAL CONDITION	START DATE	END DATE	CONTINUING
JAUNDICE	01Oct2010	Unknown	Unknown
SEROUS FLUID IN TYMPANUM	Unknown	Unknown	Yes
CRYING AT NIGHT	Unknown	Unknown	Yes
KLEBSIELLA PNEUMONIAE INFECTION	Unknown	Unknown	Yes

7. & 13. DESCRIBE EVENT(S) Sudden death, Pyrexia, Lymphadenopathy, Emphysema, Product quality issue, Cardio-respiratory arrest, Asphyxia, Febrile convulsion, This case was reported by a physician and described the occurrence of death (cause unknown) in a 10-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix Hexa, GlaxoSmithKline) for prophylaxis. The subject had no known pathology and took no concurrent medication. Vaccinal history included one dose of DTPa-IPV-Hib vaccine (Infanrixquinta, GlaxoSmithKline) administered on 31 August 2010 and one dose of tuberculosis vaccine (BCG) on 01 June 2010. The vaccination schedule of the subject did not comply with French medical authority recommendations. The subject's medical history included bronchiolitis during last winter. On 07 March 2011, the subject received a second dose of Infanrix Hexa (batch A21CA598F, route and injection site unknown). During the (See attached page)						<input checked="" type="checkbox"/> PATIENT DIED AS OUTCOME OF EVENT <input type="checkbox"/> RESULTED IN OR PROLONGED INPATIENT HOSPITALISATION <input type="checkbox"/> INVOLVED PERSISTENCE OF SIGNIFICANT DISABILITY OR INCAPACITY <input type="checkbox"/> LIFE THREATENING <input type="checkbox"/> CONGENITAL ANOMALY <input type="checkbox"/> CLINICALLY SIGNIFICANT / REQUIRED INTERVENTION <input type="checkbox"/> OTHER

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>following night, the subject experienced fever. Mobile emergency medical unit was contacted by the parents. On their arrival, the subject was dead. No diagnostic was made, sudden infant death was suspected. An autopsy was agreed by the parents (not a complete forensic). Results were not available at the time of reporting.</p> <p>According to the reporter, a causal relationship between the death and Infanrix Hexa was not established.</p> <p>Upon follow-up received from the AFFSaPS (reference T020110471A) on 22 March 2011: On 31 August 2010, tuberculosis vaccine (BCG) was made instead of 01 June 2010 (inconsistent information given). Clinical examination was normal before vaccination.</p> <p>Infanrix Hexa was administered intramuscularly at 11:00 on 07 March 2011. At 15:00, he presented with fever which resolved after paracetamol administration. The evening meal was taken without reportable incident. During the following night, fever recurred and the parents called the mobile emergency unit. On 08 March 2011, the subject was dead on mobile emergency medical unit arrival. He was found, by his father, lay on his stomach with face on his pillow. There were no signs of inhalation or vomiting. There was no sign of righting reflex, normally present at this age. Post mortem analyses were negative for C-reactive protein, blood culture and cerebrospinal fluid. Post-mortem virus tests were negative excepted positive for Respiratory Syncytial Virus in nose sample. Anatomical pathology evidenced major mesenteric adenopathy. Further informations concerning autopsy report were pending.</p> <p>According to the French method of assessment, the AFSSaPS considered the causal relationship between vaccination with Infanrix Hexa and sudden death as dubious.</p> <p>Upon follow-up received from quality department on 31 March 2011:</p> <p>A product complaint has been recorded (Ref 2011-13789). QA analysis revealed the complaint to be unsubstantiated. A complete review of the batch records had been performed and no deviation that could have an impact on the product was highlighted. A search was also performed in the GSK safety database for the final bulk A21CA598 and it did not reveal a safety signal.</p> <p>Upon follow-up received from a physician on 05 April 2011:</p> <p>The subject was born at 41 weeks of amenorrhea by normal vaginal way. He weighed 4.09 kg and measured 50 cm with a head circumference of 37 cm. APGAR scores at 1 and 5 min were at 10. No congenital abnormality or fetal distress were observed. The pregnancy occurred without problem. It was not known if the mother took any treatment during this pregnancy or during breast feeding or if she had smoked. He was breast fed until October 2010. He had a normal growth (in or upper the 97th percentile) with a normal head circumference. At the time of event, he weighed 11.34 kg. The subject had no known allergy, no know congenital metabolic or enzymatic abnormality. Medical history did not included cyanosis, respiratory arrest or apnea episodes, gastroesophageal reflux, convulsion, sleep disorder, surgery, maltreatment. Within the 2 weeks before death, the subject had no pathology including no infection, no fever, no excessive sweat during sleep, no snore during sleep, no vomiting, no modification of appetite, no diarrhea or modification of stools, no dyspnea, no abnormal crying, no lethargy. He was not admitted to emergency unit. It was unknown if he was exposed to contagious disease. The father was 25-year-old. The mother was 24-year-old and had two other children (from another father). Both had no relevant medical history. It was not known if they were smokers. The family had a city life. During the last winter, the family moved house.</p> <p>Infanrix hexa was administered intramuscularly in unknown thigh.</p> <p>The assessment of this reporter was not provided.</p> <p>Upon follow-up received from AFSSaPS on 14 April 2011:</p> <p>Autopsy results were provided and evidenced major lymphoid hyperplasia of mesenteric lymph nodes, of intestinal lymphoid tissu and of appendix with cellular dystrophy suggestive of viral etiology possibly subclinical. No Cytomegalovirus, Epstein-Barr virus or Herpes virus infection was found. At lung level, bilateral pseudo-emphysemateous pulmonary lesions were noticed, suggestive of suffocation phenomenon as no resuscitation was attempted. No sign suggestive of massive inhalation, no sign suggestive of infectious pneumopathy</p>

B0705290A	DESK COPY	(Page 3 of 3)																																																																			
<p>and no visceral congenital anomaly were reported. According to the AFSSAPS, based on the French method of assessment, the events were unlikely related to vaccination with Infanrix hexa.</p> <p>Follow-up was received on 21 April 2011 from the AFSSAPS : Psychomotor development was normal. The subject had one half-brother and one half-sister aged 6 and 5 years with medical history of convulsions. The half-brother was treated with Micropakine. On 07 March 2011, at 03:00PM, body temperature was at 39.6 Celsius degrees. On 08 March 2011, around midnight, the father still had not heard from him while he usually woke up at this time for his feed. When the father went to the bedroom, the subject was in ventral decubitus with the face on his pillow, he had cyanosis and was cold. The mobile emergency unit arrived and cardiorespiratory arrest was confirmed (the subject could not be resuscitated). His body temperature was at 35 Celsius degrees. Skull and skeleton ultrasounds were normal. The AFSSAPS reported that the respiratory syncytial virus responsibility in digestive inflammatory lesions was unlikely. Concerning the responsibility of Infanrix hexa vaccination, the administration was too recent to provide a probable explanation for the inflammation. In conclusion, no clear explanation was found to the subject death. Hypothesis of respiratory asphyxia as cause of death was made, due to circumstances in which the subject was found as well as the aspect of his lungs at autopsy. Another hypothesis was febrile convulsion.</p> <p>Post mortem tests: C reactive protein negative, CSF negative, blood culture negative and virus tests negative excepted positive for Respiratory Syncytial Virus in nose sample.</p> <p>Autopsy: -major lymphoid hyperplasia of mesenteric lymph nodes, of intestinal lymphoid tissu and of appendix with cellular dystrophy suggestive of viral etiology possibly subclinical. -no Cytomegalovirus, Epstein-Barr virus or Herpes virus infection. -bilateral pseudo-emphysemateous pulmonary lesions suggestive of suffocation phenomenon as no resuscitation was attempted. -no sign suggestive of massive inhalation. -no sign suggestive of infectious pneumopathy. -no visceral congenital anomaly.</p> <table border="0" style="width:100%;"> <tr> <td style="width:35%;">LABORATORY TEST NAME</td> <td style="width:15%;">TEST DATE</td> <td style="width:20%;">TEST RESULT</td> <td style="width:15%;">LOW NORMAL</td> <td style="width:15%;">HIGH NORMAL</td> </tr> <tr> <td>Autopsy</td> <td>Mar2011</td> <td>see text</td> <td></td> <td></td> </tr> <tr> <td>Blood culture</td> <td>08Mar2011</td> <td>negative</td> <td></td> <td></td> </tr> <tr> <td>Body temperature</td> <td>07Mar2011</td> <td>39.6Celsius degr</td> <td></td> <td></td> </tr> <tr> <td>Body temperature</td> <td>08Mar2011</td> <td>35Celsius degr</td> <td></td> <td></td> </tr> <tr> <td>C-reactive protein</td> <td>08Mar2011</td> <td>negative</td> <td></td> <td></td> </tr> <tr> <td>CSF test</td> <td>08Mar2011</td> <td>negative</td> <td></td> <td></td> </tr> <tr> <td>Full blood count</td> <td>08Mar2011</td> <td>normal</td> <td></td> <td></td> </tr> <tr> <td>Physical examination</td> <td>07Mar2011</td> <td>normal</td> <td></td> <td></td> </tr> <tr> <td>Scan NOS whole body</td> <td>08Mar2011</td> <td>normal</td> <td></td> <td></td> </tr> <tr> <td>Ultrasound skull</td> <td>08Mar2011</td> <td>normal</td> <td></td> <td></td> </tr> </table> <p>OTHER RELEVANT HISTORY</p> <p>and measured 50 cm with a head circumference of 37 cm. 7. & 13. DESCRIBE EVENT(S) Shock, Respiratory arrest, Cardiac arrest, Pyrexia, Somnolence, Hypotonia, Vomiting, Crying, Apnoea, This case was reported by a physician and described the occurrence of fatal shock in a 2-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. The subject was born by C-section. Apgar score was 10 at 0 and 5 min. Birth weight was 3.2 kg and experienced a normal growth and development. Medical condition included a possible genetic abnormality due to a family history of death after vaccination (subject's brother died 2 years ago after vaccination with DTWP). On 9 March 2011, the subject received unspecified dose of Infanrix hexa (.5 ml, unknown route of administration).					8.-12. 7. & 13. DESCRIBE EVENT(S)				
<p>state of drowsiness has been related to vaccination. Electroencephalogram was without clear anomalies irritative.</p> <p>On 23 April 2011 (night), the subject had a cardiac arrest. After 20 minutes of reanimation the cardiac activity resumed but with irreversible neurological sequelae.</p> <p>The regulatory authority reported that fever, stiff neck, fixed gaze, cold extremities, unresponsive to stimuli and cardiac arrest were possibly related to vaccination with Infanrix hexa and Prevenar 13, but almost certainly for drowsiness.</p> <p>On 25 April 2011, the subject died, cause of death is not specified. It was unknown whether an autopsy was performed.</p> <p>Follow-up information received on 19 May 2011:</p> <p>The parents of the subject were young, both were born in 1992. No information regarding important diseases or neonatal problems were reported. Artificial sucking from the early days due to maternal hypogalactia, was reported. The subject's growth had always been regular, between 50 Deg and 75 Deg percentile.</p> <p>The first dose of the vaccines Infanrix Hexa and Prevenar 13 were administered on 10 February 2011. Within weeks of vaccination with 1st dose of Infanrix Hexa and Prevenar 13, the subject experienced fever.</p> <p>An autopsy was performed and there had been no element attributed to encephalitis. The histological evaluation was in course.</p> <p>Follow-up information received on 6 September 2011:</p> <p>An autopsy was performed and the results were reported on the basis of available information and histological investigations.</p> <p>The death occurred at 15:10 on 25 April 2011.</p> <p>The death was caused by multiple organ failure, ab-ingestis pneumonia, cerebral anoxia, following sudden cardiac arrest.</p> <p>Other significant causes were not found, therefore cardiac arrest might correspond to Sudden Infant Death Syndrome (SIDS).</p> <p>There was no available scientific evidence to show a causal relationship between vaccine administrations and cardiac arrest.</p> <p>Follow-up information received on 14 September 2011:</p> <p>No concomitant medication was reported. The subject was in good health before vaccination.</p> <p>Full report on resuscitation measures and full autopsy report were not available.</p> <p>The rationale for the diagnosis of sudden infant death syndrome was as following as: since other significant causes were not found, therefore cardiac arrest was placed within a sudden infant death syndrome (SIDS).</p>

7. & 13. DESCRIBE EVENT(S) Death, This case was reported by the French regulatory authority (FR-Agence Francais de Securite Sanitaire des Produits de Sante # NT20110388) and described the occurrence of unexplained death in a 18-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. The subject had no known and relevant medical history. On 26 October 2010, the subject received an unspecified dose of Infanrix hexa (batch A21CA724A, intramuscular, injection site unknown). On 27 October 2010, 1 day after vaccination with Infanrix hexa, the subject was found dead after her nap. Autopsy did not identify any cause of death. D0070324A	DESK COPY	(Page 2 of 3)
<p>7. & 13. DESCRIBE EVENT(S)</p> <p>Less than one week post vaccination with Infanrix hexa and Prevenar 13, In January 2011, the subject experienced possible sudden infant death syndrome (SIDS).</p> <p>The subject died on an unknown date between 18 January 2011 (date of vaccination) and 24 January 2011 (date when police has informed the physician) from possible sudden infant death syndrome (SIDS). It was unknown whether an autopsy was performed.</p> <p>The reporting physician considered that the event was unlikely related to vaccination with Infanrix hexa and/or Prevenar 13.</p> <p>The case was received from Pfizer Pharma GmbH, Berlin, Germany. The other manufacturer has already reported this case under international number DE-PFIZER-INC-2011025551.</p> <p>The same case was reported on 18 February 2011 by the same physician via a sales representative and described the occurrence of death - at present cause unknown - in a 4-month-old subject of unspecified gender who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis.</p> <p>Co-suspect vaccinations included 13 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar 13, Pfizer Pharma).</p> <p>On the same unspecified date the subject received an unspecified dose of Infanrix hexa (0.5 ml, unknown) and an unspecified dose of Prevenar 13 (0.5 ml, unknown).</p> <p>Approximately three days post vaccination with Infanrix hexa and Prevenar 13, on an unspecified date, the subject was found dead in prone position lying in vomit.</p> <p>At present the cause of death was unknown. It was unknown whether an autopsy was performed.</p> <p>Follow-up information was received on 21 February 2011 from the reporting physician.</p> <p>Case D0070369A was identified as a duplicate of this case (D0070324A). Duplicate case D0070369A was voided prior to submission of any reports to regulatory authorities. All future correspondence will be submitted to this case, the case of record D0070324A.</p> <p>The subject has no underlying or concurrent medical conditions or other risk factors.</p> <p>On 18 January 2011 the subject received the first doses of Infanrix hexa (lot number: A21CA922C) and Prevenar 13.</p> <p>For the next three days following vaccination with Infanrix hexa and Prevenar 13 the subject was well.</p> <p>Then the subject died from at present unknown cause. The subject was found dead in prone position lying in vomit.</p> <p>An autopsy was performed. At the moment the result of autopsy was unknown.</p> <p>Follow-up information was received on 28 February 2011 from the reporting physician. The reported lot number for Prevenar 13 was E90728, not E40728. According to this follow-up information the subject died five days post vaccination with Infanrix hexa and Prevenar 13, on 23 January 2011, and not three days post vaccination with Infanrix hexa and Prevenar 13 as reported initially.</p> <p>The subject has no underlying or concurrent medical conditions or other risk factors. Concurrent medications included colecalciferol + sodium fluoride (D-Fluoretten) for prophylaxis and simethicone (Espumisan) as needed for infantile colic.</p> <p>On 18 January 2011 the subject received the first dose of Infanrix hexa (0.5 ml, intramuscular, left thigh) and the first dose of Prevenar 13 (0.5 ml, intramuscular, right thigh), contralaterally.</p> <p>Approximately five days post vaccination with Infanrix hexa and Prevenar 13, on 23 January 2011, the subject died from at present unknown cause. The subject received no treatment. An autopsy was performed on an unknown date, but the autopsy report was not available at the moment.</p> <p>The reporting physician considered that death from at present unknown cause was unlikely related to vaccination with Infanrix hexa and/or Prevenar 13.</p> <p>The reporting physician also provided the answers to a GSK questionnaire asking for</p>

7. & 13. DESCRIBE EVENT(S) Death, This case was reported by a health professional via a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011016343) and described death of a 3-month-old female subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) and pneumococcal vaccines (non-gsk, Prevenar 13) for prophylaxis. Previous vaccinations with Infanrix hexa and Prevenar 13 (on 14 April 2011) have been well tolerated. On 16 May 2011 the subject received the second dose of Infanrix hexa (intramuscular, unknown thigh) together with the second dose of Prevenar 13 (intramuscular, unknown thigh). In the morning of the following day, on 17 May 2011, the subject was found dead. An autopsy was performed and a preliminary autopsy report was provided. D0071496A	DESK COPY	(Page 2 of 2)																																
<p>7. & 13. DESCRIBE EVENT(S)</p> <p>morning of 17 May 2011 the subject had been found "cold and lifeless" by her parents. On 05:02 an emergency physician had been called. Cardiopulmonary resuscitation by the parents and later by the emergency personal failed and death was testified. Policemen were involved at 06:20. Interrogation of the subject's parents revealed that the subject and her four siblings had always been healthy. On 16 May 2011 the subject had received vaccinations with Infanrix hexa and Prevenar 13. At this time the subject had suffered from a mild intestinal infection. On 17 May 2011 around 0:00 the subject's mother had seen her daughter in a good condition and sleeping. Autopsy revealed signs of otitis media. Otherwise autopsy resulted normally and the cause of death could not be identified. Toxicological, microbiological, virological and histological examinations were planned.</p> <p>Follow-up information was received on 08 August 2011 via the regulatory authority by means of structured information and the final autopsy report.</p> <p>The following narrative was provided by the regulatory authority: "Follow-up information was received from the institut of legal medicine Halle (Saale) on 04 August 2011: The final autopsy report was provided. Significant findings: - affluent cerumen in the right ear, evidence of yellowish mucus in both middle ears, histological evidence of inflammatory cells - hyperaemia and cyanosis of the brain - slightly enlarged liver - bleedings at the back side of the pericardium and of the heart - bleedings at the back sides of both lungs - peritoneum in the pelvis minor with bleedings - organs without pathological findings - focal emphysematous expansion of the lung tissue (as a consequence of resuscitation) - exclusion of trauma with fatal outcome - evidence of injections at both thighs The causes and mode of of death could not be clarified. The infant had been suffering from an acute unilateral otitis media at the time of death (smear from the left middle ear: proof of Haemophilus influenzae; smear from the right middle ear: no proof of microorganisms). Within the scope of additional examinations no alcohol (alcohol concentration 0.00 %) or other pharmacologic agents (chemical-toxicologic examination without pathological findings) could be detected. There was neither evidence of an allergic reaction (total IgE 5.65 kU/l, reference <20kU/l) nor of a gastrointestinal infection. Nor was there any evidence of a postvaccinal disorder."</p> <p>According to the autopsy report, the onset date of the subject's otitis media was "very recent", but it could not be clarified whether it had been prior to or following the vaccination. Although no evidence of a relation of the event to the vaccination was found during the autopsy, the close temporal relation might be seen as an indication that the subject's death was possibly related to the vaccination with Infanrix hexa and Prevenar 13.</p> <table style="width:100%; border-collapse: collapse;"> <tr> <td style="width:35%;">LABORATORY TEST NAME</td> <td style="width:15%;">TEST DATE</td> <td style="width:20%;">TEST RESULT</td> <td style="width:20%;">LOW NORMAL</td> <td style="width:10%;">HIGH NORMAL</td> </tr> <tr> <td>Blood alcohol</td> <td>May2011</td> <td>0.00%</td> <td></td> <td></td> </tr> <tr> <td>Haemophilus influenzae test positive</td> <td>May2011</td> <td>positive</td> <td></td> <td></td> </tr> <tr> <td>IgE</td> <td>May2011</td> <td>5.65kU/l</td> <td></td> <td>20</td> </tr> </table> <table style="width:100%; border-collapse: collapse;"> <tr> <td style="width:35%;">MEDICAL CONDITION</td> <td style="width:15%;">START DATE</td> <td style="width:15%;">END DATE</td> <td style="width:35%;">CONTINUING</td> </tr> <tr> <td>INTESTINAL INFECTION</td> <td>Unknown</td> <td>Unknown</td> <td>Yes</td> </tr> <tr> <td>OTITIS MEDIA</td> <td>Unknown</td> <td>Unknown</td> <td>Yes</td> </tr> </table>			LABORATORY TEST NAME	TEST DATE	TEST RESULT	LOW NORMAL	HIGH NORMAL	Blood alcohol	May2011	0.00%			Haemophilus influenzae test positive	May2011	positive			IgE	May2011	5.65kU/l		20	MEDICAL CONDITION	START DATE	END DATE	CONTINUING	INTESTINAL INFECTION	Unknown	Unknown	Yes	OTITIS MEDIA	Unknown	Unknown	Yes

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>On 21 September 2011, 1 day after vaccination with Infanrix hexa and Prevenar, the subject experienced circulatory depression, differential diagnosis was symptoms of acute sepsis.</p> <p>The regulatory authority reported that the events were life threatening.</p> <p>The subject died from circulatory depression or possible sepsis. An autopsy was performed.</p> <p>Follow-up information was received on 28 September 2011 via the German regulatory authority (PEI).</p> <p>Infanrix hexa was given intramuscular in the left thigh and Prevenar 13 was given intramuscular in the right thigh. Different lot numbers were reported on follow-up.</p> <p>Approximately 20 hours after vaccination with Infanrix hexa and Prevenar 13, the subject experienced shock with circulatory failure.</p> <p>An emergency physician was called and the subject was hospitalized on emergency to an intensive care unit.</p> <p>Approximately 10 hours after onset of symptoms the subject died despite intensive care.</p> <p>According to follow-up information received on 07 October 2011 via the German regulatory authority (PEI), the lot number A21CB094A was documented in vaccination certificate, while there was no documentation for the mentioned lot numbers A21CB105A and A21CB115A.</p> <p>Quality test result was received on 11 October 2011. A complete review of the batch records has been performed by Quality Assurance and Production. No deviation that could impact the quality of the product has been highlighted during the GlaxoSmithKline Biologicals investigation.</p> <p>Case D0072949A was identified as a duplicate of case D0072852A and will be voided. All future correspondence will be submitted to the case of Record D0072852A.</p> <p>The duplicate case was reported by a physician, via a sales representative and stated the following:</p> <p>On 20 September 2011 in the evening, less than one day after vaccination with Infanrix hexa and Prevenar, the subject had been crying and turned grey while lying in bed. The vaccinating physician was consulted and admitted the infant to hospital, where the subject died on 21 September 2011.</p> <p>Follow-up information was received on 27 October 2011 via the German regulatory authority (PEI).</p> <p>Information about anamnesis was provided by a hospital report from intensive care treatment after birth.</p> <p>The mother had been pregnant for the first time. The mother had former surgery because of false lung vein opening and received permanent treatment with bisoprolol.</p> <p>The subject was delivered prematurely in 31+4 weeks of gestation, by section from breech presentation after pathologic CTG. There was no premature rupture of the amnion and amniotic fluid was clear. The subject had an APGAR of 6/10/10, a weight of 1490 g, length of 39 cm, head circumference of 32.6 cm, navel artery pH was 7.16.</p> <p>After birth the subject had neonatal respiratory distress syndrome grade I with continuous positive airway pressure for 24 hours.</p> <p>The subject developed possible meconium ileus due to microcolon, transient intestinal transportation disorder, cholestatic hepatitis after parenteral nutrition, with increased transaminases (alanine aminotransferase 131 U/l, aspartate aminotransferase 100 U/l, creatine kinase 342 U/l, total bilirubin 3 mg/dl, direct bilirubin 2.75 mg/dl).</p> <p>Additional diagnoses after birth included neonatal anemia and iron deficiency, asymmetry from lying, small hemangioma right gluteal and dystrophic growth and weight increase.</p> <p>On the sixth day of life, the subject's condition worsened and he was transferred to an intensive care unit for neonates. Intravenous antibiotics were given for seven days.</p> <p>The subject had abdominal distension since birth and not yet passed meconium. Acute abdomen was suspected on the seventh day of life. The subject was transferred to a pediatric surgical unit for further intervention, but after conservative treatment the symptoms resolved.</p> <p>Test results were normal for ions, blood gases, immune reactive trypsin (tested on 06 May and 06 June 2011), sonogram of head, abdomen and hip (Graf classification Ib) and hearing screening. Cytomegalovirus (CMV) and toxoplasmosis IgM and IgG antibodies were negative. Initially increased Thyroid stimulating hormone normalised on control. Bile acid was</p>

increased (74.6 mcmol/l), pancreatic kinase was decreased (68 mcg/g). Eye examination showed vascularisation limit zone III at both sides.
The subject was discharged after 39 days in good condition and received rachitis prophylaxis and iron substitution.

No further details about the reported event were provided.

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>This was all the available information. The reporter will send additional details in a proactive way.</p> <p>Follow up information received on 2 July 2009 from regulatory authority: The subject had no medical history and no concomitant medication. On 16 June 2009 the subject received 1st dose of Infanrix hexa (unknown route), 1st dose of Prevenar (unknown route).</p> <p>1 day after vaccination with Infanrix hexa and Prevenar, the subject was found in bed nonresponsive, floppy and pale.</p> <p>The subject died on 17 June 2009, cause of death was not reported.</p> <p>Follow up information received on 4 November 2010:</p> <p>The subject's medical history included fetal distress (emergency cesarean section at 36 weeks). Birth weight 2250 g. Apgar after 1 minute 7, after 5 minutes 8 while being respiration. Oxygen saturation after 1 minute: 77 - 88 %. Low blood pressure: 44/20 and 66/40. Hemoglobin after birth 2,0 after which she received two transfusions with erythrocytes and then Hemoglobin 5,2 mmol/l.</p> <p>The baby was checked in hospital at 2.5 week-old: growth and development good.</p> <p>At age 4 and 8 weeks (8 weeks = 16 June 2009), the subject was checked at child health clinic and showed a normal development and growth.</p> <p>On 16 June 2009 at 16:00, the subject received 1st dose of Infanrix hexa and 1st dose of Prevenar.</p> <p>The baby was fed during the night at 4:00 and she was normal. The subject was found dead in bed lying at side with free airway at 8:45. An autopsy was performed and showed no indications for cause of death, therefore conclusion was cot death, relation with vaccination was not possible to assess.</p> <p>The healthcare professional considered the events were clinically significant (or requiring intervention).</p> <p>Follow up information received on 17 November 2010:</p> <p>The subject's medical history included anemia; hemoglobin was 2.2 mmol/L. After erythrocyte transfusion, hemoglobin was 5.2 mmol/L.</p> <p>Cardiopulmonary resuscitation (CPR) was started by the parents. Ambulance was called and after 1 hour the CPR was stopped at the hospital. Letter from pediatrician revealed no abnormalities in post mortal examinations. Possible hypothesis was choking due to aspiration. Conclusion was sudden infant death syndrome.</p> <p>The regulatory authority considered the events were unlikely to be related to vaccination with Infanrix hexa and Prevenar.</p> <p>No further information was available.</p> <table border="0"> <tr> <td>MEDICAL CONDITION</td> <td>START DATE</td> <td>END DATE</td> <td>CONTINUING</td> </tr> <tr> <td>EMERGENCY CESAREAN SECTION AT 36 WE</td> <td>Unknown</td> <td>Unknown</td> <td>Unknown</td> </tr> <tr> <td>ANEMIA REQUIRING TRANSFUSION</td> <td>Unknown</td> <td>Unknown</td> <td>Unknown</td> </tr> </table>			MEDICAL CONDITION	START DATE	END DATE	CONTINUING	EMERGENCY CESAREAN SECTION AT 36 WE	Unknown	Unknown	Unknown	ANEMIA REQUIRING TRANSFUSION	Unknown	Unknown	Unknown

7. & 13. DESCRIBE EVENT(S)

On 16 November 2009, 4 days after vaccination with Infanrix hexa and Prevenar, the subject was brought to day care centre. He had no fever. He burped well after being fed and put into bed at 9:25 lying on abdomen (with permission mother). Every 20 minutes, the baby was checked. At 12:00, the subject was nonresponsive and had blood in mouth.

Reanimation was started immediately, 3 times adrenaline (Epinephrine) and sodium chloride (NaCl), and oxygen.

The child arrived at hospital, reanimation was proceeded by intubation, no output. Echocardiography showed no activity, resuscitation was stopped.

The subject died on 16 November 2009 from sudden infant death syndrome.

An autopsy was performed and showed the following: In lungs, fluid retention (consolidations). Boy was normally developed with head circumference and weight far above average. Weight of lungs 184g, normal is 65g. Neuropathologic examinations revealed no abnormalities.

Brain edema which terminally occurred and signs of blood damming were present.

General conclusion: no cause of death found in autopsy or toxicological investigations.

Tryptase: 4.2 mcg/l blood from heart (normal: lower than 11.5 mcg/l for adults).

No indication for anaphylactic reaction. In addition, time period of 4 days is too long to suspect an anaphylactic reaction.

No indications for a relation with vaccinations.

No further information was available.

On 21 October 2011, 8 days after vaccination with Infanrix hexa, Prevenar and Rotarix, the subject experienced fever and diarrhea. The subject was hospitalised. The subject died in the night 21 and 22 October 2011 from septicemia. It was unknown whether an autopsy was performed. The subject's twin sister had received the same vaccination without problem. Information inadvertently not recorded in the initial report: The event septicemia was added.

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>Follow-up information received on 30 November 2011 and 2 December 2011 from 2 newspapers and from a consumer via a web forum:</p> <p>The mother's medical history included allergy and the family history included baby sudden death. The organisation who administered the vaccines was not aware that the subject had a cold.</p> <p>When the subject developed fever (39.9 deg.C) on 21 October 2011, the subject was treated by her parents with an antipyretic drug (suppository) and was taken to the hospital.</p> <p>At the hospital, gastroenteritis was firstly diagnosed, and after this diagnosis was changed to a pulmonary infection. The subject was treated with an antibiotic. But at 11 pm, her body was covered with purpura. The subject died at about 3 o'clock in the morning on 22 October 2011, 9 hours after she arrived at the hospital. Her body was covered with blue plaques.</p> <p>The diagnosis of purpura fulminans reported. The consumer also reported that rapid meningococcal meningitidis was mentioned, but no lumbar puncture and no hemoculture were performed therefore they could not conclude to this diagnosis.</p> <p>The subject's parents lodged a complaint against "X" because of the lack of information provided before the vaccination about the risks and the lack of precaution taken regarding the family history.</p> <p>The subject's twin sister of this case also experienced an adverse event after vaccination with same vaccines. At an unspecified time following vaccination with Infanrix hexa, Prevenar and Rotarix, the subject's twin sister experienced apnea. At the time of reporting, the event was improved. Please see case B0767303A for details about the subject's twin sister.</p> <table style="width:100%; border: none;"> <tr> <td style="width:35%;">LABORATORY TEST NAME</td> <td style="width:15%;">TEST DATE</td> <td style="width:20%;">TEST RESULT</td> <td style="width:20%;">LOW NORMAL</td> <td style="width:10%;">HIGH NORMAL</td> </tr> <tr> <td>Body temperature</td> <td>21Oct2011</td> <td>39.9deg.C</td> <td></td> <td></td> </tr> <tr> <td>MEDICAL CONDITION</td> <td>START DATE</td> <td>END DATE</td> <td colspan="2">CONTINUING</td> </tr> <tr> <td>COLD</td> <td>Unknown</td> <td>Unknown</td> <td colspan="2">Unknown</td> </tr> <tr> <td>PREMATURE BIRTH</td> <td>Unknown</td> <td>Unknown</td> <td colspan="2">Unknown</td> </tr> </table>			LABORATORY TEST NAME	TEST DATE	TEST RESULT	LOW NORMAL	HIGH NORMAL	Body temperature	21Oct2011	39.9deg.C			MEDICAL CONDITION	START DATE	END DATE	CONTINUING		COLD	Unknown	Unknown	Unknown		PREMATURE BIRTH	Unknown	Unknown	Unknown

DESCRIBE EVENT(S) Respiratory failure, Shock, Cardiovascular insufficiency, Screaming, Pallor, Restlessness, Renal failure, Hyperkalaemia, Pneumonia viral, Rash macular, Sinus tachycardia, Anuria, Vomiting, Hypotonia, Irritability, Faeces discoloured, Lactic acidosis, This case was reported by a regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2011030856) and described the occurrence of respiratory failure in a 5-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccination included 13-valent pneumococcal vaccine (non-GSK) (Prevenar 13, Pfizer). First vaccination with both vaccines on 23 August 2011 was well tolerated. Information on medical history and concomitant medication was not provided. D0072852A	DESK COPY	(Page 2 of 4)
<p>7. & 13. DESCRIBE EVENT(S)</p> <p>On 20 September 2011 the subject received 2nd dose of Infanrix hexa (unknown route and application site), 2nd dose of Prevenar (unknown route and application site).</p> <p>On 21 September 2011, 1 day after vaccination with Infanrix hexa and Prevenar, the subject experienced circulatory depression, differential diagnosis was symptoms of acute sepsis.</p> <p>The regulatory authority reported that the events were life threatening.</p> <p>The subject died from circulatory depression or possible sepsis. An autopsy was performed.</p> <p>Follow-up information was received on 28 September 2011 via the German regulatory authority (PEI).</p> <p>Infanrix hexa was given intramuscular in the left thigh and Prevenar 13 was given intramuscular in the right thigh. Different lot numbers were reported on follow-up.</p> <p>Approximately 20 hours after vaccination with Infanrix hexa and Prevenar 13, the subject experienced shock with circulatory failure.</p> <p>An emergency physician was called and the subject was hospitalized on emergency to an intensive care unit.</p> <p>Approximately 10 hours after onset of symptoms the subject died despite intensive care.</p> <p>According to follow-up information received on 07 October 2011 via the German regulatory authority (PEI), the lot number A21CB094A was documented in vaccination certificate, while there was no documentation for the mentioned lot numbers A21CB105A and A21CB115A.</p> <p>Quality test result was received on 11 October 2011. A complete review of the batch records has been performed by Quality Assurance and Production. No deviation that could impact the quality of the product has been highlighted during the GlaxoSmithKline Biologicals investigation.</p> <p>Case D0072949A was identified as a duplicate of case D0072852A and will be voided. All future correspondence will be submitted to the case of Record D0072852A.</p> <p>The duplicate case was reported by a physician, via a sales representative and stated the following:</p> <p>On 20 September 2011 in the evening, less than one day after vaccination with Infanrix hexa and Prevenar, the subject had been crying and turned grey while lying in bed. The vaccinating physician was consulted and admitted the infant to hospital, where the subject died on 21 September 2011.</p> <p>Follow-up information was received on 27 October 2011 via the German regulatory authority (PEI).</p> <p>Information about anamnesis was provided by a hospital report from intensive care treatment after birth.</p> <p>The mother had been pregnant for the first time. The mother had former surgery because of false lung vein opening and received permanent treatment with bisoprolol.</p> <p>The subject was delivered prematurely in 31+4 weeks of gestation, by section from breech presentation after pathologic CTG. There was no premature rupture of the amnion and amniotic fluid was clear. The subject had an APGAR of 6/10/10, a weight of 1490 g, length of 39 cm, head circumference of 32.6 cm, navel artery pH was 7.16.</p> <p>After birth the subject had neonatal respiratory distress syndrome grade I with continuous positive airway pressure for 24 hours.</p> <p>The subject developed possible meconium ileus due to microcolon, transient intestinal transportation disorder, cholestatic hepatitis after parenteral nutrition, with increased transaminases (alanine aminotransferase 131 U/l, aspartate aminotransferase 100 U/l, creatine kinase 342 U/l, total bilirubin 3 mg/dl, direct bilirubin 2.75 mg/dl).</p> <p>Additional diagnoses after birth included neonatal anemia and iron deficiency, asymmetry from lying, small hemangioma right gluteal and dystrophic growth and weight increase.</p> <p>On the sixth day of life, the subject's condition worsened and he was transferred to an intensive care unit for neonates. Intravenous antibiotics were given for seven days.</p> <p>The subject had abdominal distension since birth and not yet passed meconium. Acute abdomen was suspected on the seventh day of life. The subject was transferred to a pediatric surgical unit for further intervention, but after conservative treatment the symptoms resolved.</p> <p>Test results were normal for ions, blood gases, immune reactive trypsin (tested on 06 May and 06 June 2011), sonogram of head, abdomen and hip (Graf classification Ib) and hearing</p>

<p>screening. Cytomegalovirus (CMV) and toxoplasmosis IgM and IgG antibodies were negative. Initially increased Thyroid stimulating hormone normalised on control. Bile acid was increased (74.6 mmol/l), pancreatic kinase was decreased (68 mcg/g). Eye examination showed vascularisation limit zone III at both sides.</p> <p>The subject was discharged after 39 days in good condition and received rachitis prophylaxis and iron substitution.</p> <p>No further details about the reported event were provided.</p> <p>An autopsy report was received via the German regulatory authority (PEI) on 09 December 2011.</p> <p>Autopsy was performed on 23 September 2011.</p> <p>According to the report, events after vaccination also included nocturnal restlessness, increasing pallor, renal failure and hyperkalemia.</p> <p>Pre-existing underlying medical condition included subacute florid lymphocytic interstitial pneumonia, probably of viral origin, significant activation of the bronchio-alveolar lymphatic system, accumulation of alveolar macrophages, focal beginning alveolar reaction, capillary ectasia and occlusion of the big bronchia by mucus.</p> <p>The cause of death was identified as respiratory failure with protracted shock due to interstitial pneumonia, probably of viral origin. Pathogenic microorganisms were not detected.</p> <p>Evidences of shock included Paltauf dots at the pleura visceralis, fresh necrosis of the kidneys, disseminated hemorrhage of the small intestine, hemorrhage of the mucous membrane of the stomach, multiple stasis hemorrhage of the spleen.</p> <p>Additional findings showed macular exanthema situated at the right lower leg and cervical and para-oesophageal soft tissue hemorrhage.</p> <p>There was no reaction at the injection site.</p> <p>Hemorrhages were also considered to be caused by intensive care measures.</p> <p>Follow-up received on 12 December 2011 included a complete hospital report.</p> <p>The subject was hospitalized on 21 September 2011 at 09:30.</p> <p>In hospital the subject was diagnosed with death after ventricular tachycardia with hyperkalemia and acute circulatory shock of unclear genesis with anuria and hyperkalemia.</p> <p>According to the hospital report, the subject had developed normally within the last months. Childhood examination U4 (performed in 3rd to 4th month of life) showed anemia (hemoglobin 8.5 g/dl).</p> <p>The subject's mother had arterial hypertension and received bisoprolol. She formerly underwent surgery because of wrong lung vein ostium.</p> <p>After the subject had received the vaccinations, there was nothing abnormal during the day. In the night, around 01:00 o'clock the subject had been drinking about 200 ml.</p> <p>At 03:00 the subject started crying, which increased despite treatment with simethicone (Sab). He was vomiting twice. There was a transient improvement after receiving caraway suppository at 05:00.</p> <p>In the morning the subject became pale with strange breathing.</p> <p>When hospitalized, the subject was in bad condition, with circulatory depression, tachycardia with heart rate over 210 per min, pallor, muscle hypotonia, high irritability, moaning breathing. Green stool was excreted once.</p> <p>Supraventricular tachycardia could be excluded by electrocardiogram (ECG), which showed sinus tachycardia.</p> <p>Blood gas analysis showed acidosis with increased lactate and potassium. The subject received volume bolus via infusion on the head.</p> <p>After sudden worsening of condition with fall in oxygen saturation the subject received ketamine and diazepam.</p> <p>There was a short phase of bradycardia with the need for cardiac massage.</p> <p>The subject received further volume via intra-osseous access, as well as dobutamine, adrenaline (Adrenalin), claforan for suspected sepsis and hydrocortisone for circulatory support.</p> <p>Echocardiogram excluded dilated cardiomyopathy, but showed reduced pump function of heart.</p> <p>Sonogram of head excluded acute bleeding. Abdominal sonogram was normal.</p> <p>The subject's body temperature had decreased to 33.1 degC rectal and exogenous warmth treatment was started.</p> <p>Blood test results challenged the diagnosis of sepsis, without fever and with no relevant</p>

D0072852A	DESK COPY		(Page 4 of 4)	
<p>inflammatory signs. Ammonia was increased, which was considered a possible sign for metabolic disorder.</p> <p>The subject received central vein catheter in V. jugularis interna and arterial catheter in V. femoralis at the right, but no stabilization could be achieved. Katecholamines were increased.</p> <p>The subject still had no diuresis and was treated with frusemide (Lasix).</p> <p>In further course the subject developed increasing potassium values, T-wave elevation, ventricular tachycardia, anuria and no improvement of the situation. Further treatment was without success.</p> <p>At 16:20 further cardiac problems developed, but because of the bad situation no defibrillation was started. The subject died at 16:21 in the parent's presence.</p> <p>The hospital physician stated that after exclusion of cardiac, cerebral and abdominal causes, the event was most likely an atypical sepsis without fever and inflammatory signs. However, postmortal cultures of blood and cerebrospinal fluid also showed no germs.</p> <p>Despite of the autopsy results, the cause of death still kept unclear for the hospital physician. He stated that there were no radiologic signs for pneumonia and artificial respiration had been successful, with normalization of blood gas values.</p> <p>A metabolic disorder was considered possible, but it was more likely that lactic acidosis and hyperammonia were a secondary effect of shock.</p>

Infanrix hexa™

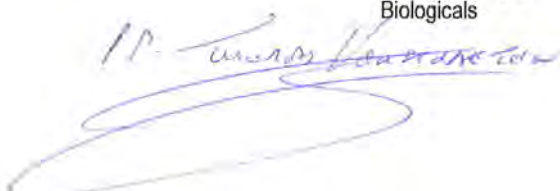

Safety Update

International Birthdate: 23 October 2000 (European Union)

Data Lock Points: 23 October 2009 to 22 October 2010

Author Dominique Parmentier Safety Scientist

Report No 15 - 16 December 2010

Reviewer	Thomas Breuer, MD	Senior Vice President Head of Global Vaccines Development, GSK Biologicals	Date <i>16/12/10</i>
			

EXECUTIVE SUMMARY

- Infanrix hexa is currently registered in 88 countries. Worldwide Marketing Authorisation status for Infanrix hexa is provided in Appendix 1A.
- During the period under review, no regulatory actions have been taken for safety reasons.
- Post-marketing exposure to Infanrix hexa during the PSUR reporting period is estimated to be between 2,995,430 and 11,981,722 subjects. Number of subjects exposed since launch until the Data Lock Point (DLP) of this report is estimated as being between 15,156,658 and 60,626,633.
- The data received during the reporting period referred to a total of 2080 reports of which 1216 cases fulfilled the ICH E2C criteria for inclusion in the main line listings and summary tabulations of this report.
- Amendments to the Reference Safety Information (RSI) made during the reporting period include addition of a warning statement about “syncope”: “Syncope (fainting) can occur following, or even before, any vaccination as a psychogenic response to the needle injection. It is important that procedures are in place to avoid injury from faints”.
- No further amendments to the RSI are considered necessary at the present time.
- The benefit/risk profile of Infanrix hexa™ continues to be favourable.
- The Company will continue to monitor all cases of thrombocytopenia, injection site nodule and nodule, anaphylaxis, abscess and injection site abscess, important neurological events including encephalitis and encephalopathy, erythema multiforme, Henoch-Schonlein purpura, petechiae and purpura.

1. INTRODUCTION

This is the 15th Periodic Safety Update Report (PSUR) for Infanrix hexa™ which covers the reporting period 23 October 2009 to 22 October 2010.

This PSUR covers all formulations and indications for the product(s) and is prepared according to all applicable regulations [ICH, 1996; ICH, 2003; Volume 9A, 2008; CHMP/PhVWP, 2007; EMEA/CHMP, 2006].

1.1. Pharmacology and Indications

Infanrix hexa™ contains the following antigens adsorbed onto aluminium salts: diphtheria toxoid, tetanus toxoid, three purified pertussis antigens [pertussis toxoid (PT), filamentous haemagglutinin (FHA) and pertactin (PRN; 69 kiloDalton outer membrane protein)], the purified major surface antigen (HBsAg) of the hepatitis B virus (HBV) and purified polyribosyl-ribitol-phosphate capsular polysaccharide (PRP) of Haemophilus influenzae type b (Hib), covalently bound to tetanus toxoid. It also contains three types of inactivated polio viruses (type 1: Mahoney strain; type 2: MEF-1 strain; type 3: Saukett strain).

The tetanus and diphtheria toxoids are obtained by formaldehyde treatment of purified Corynebacterium diphtheriae and Clostridium tetani toxins. The acellular pertussis vaccine components are obtained by extraction and purification from phase I Bordetella pertussis cultures, followed by irreversible detoxification of the pertussis toxin by glutaraldehyde and formaldehyde treatment, and formaldehyde treatment of FHA and PRN. The diphtheria toxoid, tetanus toxoid and acellular pertussis components are adsorbed onto aluminium salts.

The surface antigen of the HBV is produced by culture of genetically-engineered yeast cells (Saccharomyces cerevisiae) which carry the gene coding for the major surface antigen of the HBV. This HBsAg expressed in yeast cells is purified by several physico-chemical steps. The HBsAg assembles spontaneously, in the absence of chemical treatment, into spherical particles of 20 nm in average diameter containing non-glycosylated HBsAg polypeptide and a lipid matrix consisting mainly of phospholipids. Extensive tests have demonstrated that these particles display the characteristic properties of the natural HBsAg.

The three polioviruses are cultivated on a continuous VERO cell line, purified and inactivated with formaldehyde.

The Hib polysaccharide is prepared from Hib, strain 20,752 and after activation with cyanogen bromide and derivatisation with an adipic hydrazide spacer is coupled to tetanus toxoid via carbodiimide condensation. After purification the conjugate is adsorbed on aluminium salt, and then lyophilised in the presence of lactose as stabiliser. Infanrix hexa™ meets the World Health Organisation requirements for manufacture of biological substances, of diphtheria, tetanus, pertussis and combined vaccines, of hepatitis B vaccines made by recombinant DNA techniques, of inactivated poliomyelitis vaccines and of Hib conjugate vaccines.

CONFIDENTIAL

CONFIDENTIAL

Infanrix hexa™ is indicated for primary and booster immunisation against diphtheria, tetanus, pertussis, hepatitis B, poliomyelitis and *Haemophilus influenzae* type b in infants from the age of 6 weeks and may be given to infants who received a first dose of hepatitis B vaccine at birth.

The primary vaccination schedule (such as 2, 3, 4 months; 3, 4, 5 months; 2, 4, 6 months; 3, 5 and 11 or 12 months; 6, 10, 14 weeks) consists of three doses of 0.5 ml. An interval of at least one month should be respected between doses.

If it is intended to administer Infanrix hexa™ according to the EPI schedule (Expanded Program on Immunisation; 6, 10, 14 weeks of age), then the vaccinee must receive a dose of hepatitis B vaccine at birth.

1.2. Presentations

A 0.5 ml dose of the vaccine contains not less than 30 IU of adsorbed diphtheria toxoid, not less than 40 IU of adsorbed tetanus toxoid, 25 mcg of adsorbed PT, 25 mcg of adsorbed FHA, 8 mcg of adsorbed pertactin, 10 mcg of adsorbed recombinant HBsAg protein, 40 D-antigen units of type 1 (Mahoney), 8 D-antigen units of type 2 (MEF-1) and 32 D-antigen units of type 3 (Saukett) of the polio virus. It also contains 10 mcg of adsorbed purified capsular polysaccharide of Hib (PRP) covalently bound to 20-40 mcg tetanus toxoid (T).

2. WORLDWIDE MARKET AUTHORISATION STATUS

Infanrix hexa™ was first approved in the Europe Union on 23 October 2000 (centralised procedure) and is currently licensed in 88 countries. Details of all countries where Infanrix hexa™ is currently approved are presented in Appendix 1A. Details of countries where the marketing authorisations have been withdrawn are presented in Appendix 1B.

3. UPDATE OF REGULATORY AUTHORITY OR MARKETING AUTHORISATION HOLDER ACTIONS TAKEN FOR SAFETY REASONS

During the period under review, no actions have been taken for safety reasons concerning withdrawal, revocation, rejection, suspension or failure to obtain a renewal of a Marketing Authorisation; neither have there been any dosage modifications, changes in target population, formulation changes, restriction on distribution, or clinical trial suspension.

4. CHANGES TO REFERENCE SAFETY INFORMATION

Changes to the Reference Safety Information (RSI), including rationale, are communicated to Regulatory Agencies on an ongoing basis.

The RSI in effect at the beginning of the reporting period is presented in Appendix 2A.

The RSI is the Global Prescriber Information (GPI) of the Global Datasheet (GDS) version number 10 dated 21 October 2010; the Core Safety Information (CSI) is highlighted in this document by shaded text.

Changes to the CSI during the reporting period include the following:

Addition of a warning statement about “syncope” in all injectable vaccines: *Syncope (fainting) can occur following, or even before, any vaccination as a psychogenic response to the needle injection. It is important that procedures are in place to avoid injury from faints.*

The RSI in effect at the end of the reporting period is presented in Appendix 2B.

5. PATIENT EXPOSURE

5.1. Market Experience

An estimation of the total patient exposure can be calculated from the number of doses distributed, which is the only data available with regard to patient exposure in a post-marketing setting. The assumption is made that one dose distributed will equal one subject exposed to vaccination.

It is important to note that the sales database from which data are issued is an in-house „living“ database and is subject to updates and corrections depending on information provided by GSK local country subsidiaries (e.g. some vaccine batches may be returned to GSK central office). In the sales database, corrections and updates are posted on related period/month and therefore, could be slightly different from original PSUR data. Donations are not included.

During the period covered by this report 11,981,722 doses of Infanrix hexa™ have been distributed. Since launch until the data lock point (DLP) of this PSUR, 60,626,633 doses have been distributed. As vaccination with Infanrix hexa™ could vary between 1 and 4 doses per subject in accordance with local recommendations, post-marketing exposure to Infanrix hexa™ during the PSUR reporting period is estimated to be between 2,995,430 and 11,981,722 subjects. The number of subjects exposed since launch until the data lock point of this report is estimated as being between 15,156,658 and 60,626,633.

The market experience during the reporting period of this PSUR is comparable to that of the previous reporting period.

6. INDIVIDUAL CASE HISTORIES

6.1. Definitions

LISTEDNESS

Listedness is automatically assigned by GSK at the MedDRA Preferred Term (PT) level.

An event is only considered listed if it is included in the CCSI under all circumstances. Events that are only listed in specific situations (e.g. in overdose, for a specific indication, as part of a hypersensitivity reaction or post-treatment) are assessed as „unlisted“. Lack of efficacy is assessed as listed. This is supported by CIOMS V which acknowledges that no vaccine can be expected to be effective in all patients.

Listed Case:

A case is considered listed if all Adverse Events (AEs) are covered by the Company Core Safety Information (CCSI) when it is entered onto the safety database. This may be different from the RSI used for this PSUR. Note: For clinical trials and PMS cases, only serious, attributable events must be in the CSI for the case to appear as listed.

Unlisted Case:

A case where at least one AE was not covered by the CSI at the time of case entry.

SERIOUSNESS

Serious Case:

A case involving an untoward medical occurrence that results in death, is life-threatening, requires hospitalisation or prolongation of existing hospitalisation, results in disability/incapacity or is a congenital anomaly/birth defect.

Medical or scientific judgement is exercised in deciding whether other reports should also be considered serious, such as those involving important medical events that may not be immediately life-threatening or result in death or hospitalisation but may jeopardise the subject or may require medical or surgical intervention to prevent one of the other outcomes listed in the above definition. These events are also considered serious. Examples of such events are invasive or malignant cancers, intensive treatment in an emergency room or at home for allergic bronchospasm, blood dyscrasias, convulsions that do not result in hospitalisation, or development of drug dependency or drug abuse. In GSK, such medically important events are termed GSK „medically serious AEs“ (see below).

GSK Medically Serious AE:

As proposed by CIOMS V, GSK maintains a list of all events considered to be „medically serious“ that is regularly reviewed and updated by the company Safety Physicians. This list of MedDRA Lower Level Terms (LLTs) is automatically applied to all spontaneous, post-marketing and literature cases as they are entered onto the safety database. Inclusion of „medically serious“ events makes the case serious at case level.

Other Definitions

Attributability:

A clinical trial case is classified as „attributable“ if the investigator or the company consider there is a reasonable possibility that a serious AE was caused by the study medication. These cases may also contain individual non-serious AEs. A clinical trial case is also considered „attributable“ if the investigator does not specify causality for any serious AE.

Primary Adverse Event:

The main AE described by the reporter. If a diagnosis and associated signs/symptoms have been provided, GSK will consider the diagnosis the primary AE. Where the main AE is not clear, GSK assigns the most serious medical condition the reporter thought was associated with the drug as the primary AE.

6.2. Cases Presented as Line Listings

The following type of cases received by GSK from worldwide sources during the reporting period and referenced below are considered to fulfil ICH E2C criteria for inclusion in the main line listings and/or summary tabulations of this report:

- all serious adverse reactions and non-serious unlisted adverse reactions from spontaneous notifications (including published reports);
- all non-serious listed adverse reactions from spontaneous reporting;
- all serious adverse reactions (attributable to the vaccine by either investigator or sponsor) available from studies or named-patient/compassionate use;
- all serious adverse reactions from regulatory authorities.

In addition, the type of cases mentioned below is included as a line listing as well:

- all serious and non-serious (listed and unlisted) adverse reactions reported by patients/consumers and other non-healthcare professionals (non-medically verified cases).

CONFIDENTIAL

CONFIDENTIAL

The type of cases making up the PSUR line listings within Appendices 3 is summarised below and in Table 1.

Appendix 3A contains:

- all serious cases from spontaneous notifications (including published reports and regulatory reports but excluding non-medically verified reports);
- all unblinded serious cases arising from clinical trials considered related by sponsor or investigator;
- all non-serious unlisted cases from spontaneous notifications (including published reports but excluding non-medically verified reports and reports received solely from regulatory authorities).

Appendix 3B contains all serious attributable clinical trial cases unblinded during the reporting period which were not included in a previous report because they were still blinded.

It is company policy that only those clinical trial reports which are expedited to regulatory authorities are unblinded on the safety database during study conduct. Clinical trial reports that are not expedited will be unblinded on study completion. Any clinical trial reports meeting ICH E2C criteria but not included in a previous PSUR, are included as follow-up information in Appendix 3B.

In order to ensure no cases are missed, GSK uses a broad search strategy to retrieve clinical trial cases unblinded during the reporting period. Therefore, Appendix 3B may include some cases which have already been included in a previous PSUR (e.g. non-blinded clinical trial cases).

Appendix 3C contains all non-serious listed cases from spontaneous notifications including published reports but excluding all non-medically verified reports and all reports received solely from regulatory authorities.

Appendix 3D contains all non-medically verified cases, whether serious or non-serious, listed or unlisted.

Table 1 Appended Line Listings

Format	Appendix	Case Type
Line Listing	3A	All serious spontaneous cases (excluding consumer reports), all serious attributable clinical trial cases and all non-serious unlisted cases (excluding consumer and regulatory reports)
	3B	All serious attributable clinical trial cases which were received prior to the period of this PSUR but unblinded during the reporting period. <i>No cases have been received so Appendix 3B is empty.</i>
	3C	All non-serious listed cases (excluding consumer and regulatory authority reports)
	3D	All non-medically verified cases

Explanation of line listings content

Within the line listings a case is considered serious if it fulfils the ICH definition of serious (see section 6.1). Serious cases are identified by a “#” beside the case ID.

An unlisted case contains at least one AE that is not covered by the CSI which was in place at the time of data entry.

The AEs within a case are presented at MedDRA PT level. System Organ Class (SOC) is assigned automatically according to the Primary AE.

Literature citations for all published cases are noted in the „Comments” column of the line listing.

6.3. Cases Presented as Summary Tabulations

An aggregate summary for each of the line-listings is presented in Appendices 4 as summarised below and in Table 2. All AEs are presented at MedDRA PT level within summary tabulations.

Appendix 4A contains all reported adverse events for cases included in Appendix 3A, meaning adverse events from all serious spontaneous cases (excluding consumer reports), all serious attributable clinical trial cases and all non-serious unlisted cases (excluding consumer and regulatory reports).

Appendix 4B contains all reported adverse events for cases included in Appendix 3C, meaning adverse events from all non-serious listed cases (excluding consumer and regulatory authority reports).

Appendix 4C contains all reported adverse events from non-medically verified serious cases + non-medically verified non-serious unlisted cases.

Appendix 4D contains all reported adverse events from non-medically verified non-serious listed cases.

Appendix 4E is a cumulative tabulation of all unlisted events from serious unlisted spontaneous reports (including non-medically verified reports) and all serious unlisted reactions from clinical trial cases reported since launch.

Of note, differences may appear between numbers in the previous PSUR cumulative counts of unlisted events for the following reasons:

- changes in the listedness of some adverse events due to an update in the Reference Safety Information;
- increased consistency in the listedness assessment has been achieved following implementation of an automated listedness attribution applied to the case reports received;
- in “old” cases diagnostics could have been coded with signs and symptoms. These signs and symptoms are not included in the cumulative count anymore.
- in the previous tables all adverse events, listed and unlisted were taken into account while in the new outputs, only the unlisted adverse events are provided.

Table 2 Appended Summary Tabulations

Summary Tabulation	4A	All reported AEs for cases included in Appendix 3A
	4B	All reported AEs for cases included in Appendix 3C
	4C	All reported AEs from non-medically verified serious cases and non-serious unlisted cases
	4D	All reported AEs from non-medically verified non-serious listed cases
	4E	Cumulative tabulation of all unlisted events from serious unlisted spontaneous reports and all serious unlisted reactions from clinical trial cases reported since launch

Explanation of summary tabulations content

The following information is important when evaluating the summary tabulations.

Seriousness

Adverse events from spontaneous, post-marketing or literature cases are only classified as serious within the tabulations if they are on the list of GSK medically serious terms (see Section 6.1). Therefore, although an AE may reside in a case that fulfils the ICH criteria of serious, if the event is not on the list of GSK medically serious terms it will appear within the non-serious column in the summary tabulations.

GSK believes that applying the GSK medically seriousness criteria to AEs will provide a consistent and more meaningful presentation of data within the tabulations, and help with aggregation of terms for signal review activities. Counts of events are presented in the tabulations for the reporting period of the PSUR and cumulatively (Appendix 4E).

Note: In rare situations an event may appear in both the serious and non serious columns within the summary tabulations, this may occur for the following reasons:

- *GSK only applies its list of medically serious terms to events reported in spontaneous reports, literature cases and post-marketing surveillance studies. Serious criteria for events originating from clinical trial cases are determined by the reporter. Therefore, as events can originate from different report sources seriousness assessments may differ.*
- *The GSK medically serious list is compiled at the MedDRA LLT level. Summary tabulations present counts of events at the MedDRA PT level. A PT may therefore have both serious and non serious LLTs associated with it.*

CONFIDENTIAL

CONFIDENTIAL

Overview

An overview of the 2080 reports received in the time period is presented below.

Table 3 Reports received in Time Period of PSUR

REPORTS FULFILLING ICH E2C CRITERIA	NUMBER OF CASES
Serious Unlisted	465
Serious Listed	48
Non-serious Unlisted	649
Non-Serious Listed	54
TOTAL (ICH E2C criteria)	1216
OTHER REPORTS	
Non-Medically Verified	289
Regulatory, non-serious	575
TOTAL (Other reports)	864

GRAND TOTAL (All reports)	2080
----------------------------------	-------------

The 2080 reports were received from 41 countries, mainly France (645 reports, 31%), Italy (602 reports, 28.9%) and Germany (339 reports, 16.3%).

Based on the initial reporting source, 783 cases were received from healthcare professionals and 1297 cases by non-healthcare professionals (consumers, regulatory authorities, representatives, literature, other).

CONFIDENTIAL

CONFIDENTIAL

Table 4 shows the numbers of AEs by System Organ Class (SOC) for the whole dataset of cases received in the time period.

Table 4 **Table of all AEs by SOC for all cases received in the time period of the PSUR**

System Organ Class	Number of Cases
General disorders and administration site conditions	666 (32%)
Injury, poisoning and procedural complications	639 (30.7%)
Nervous system disorders	280 (13.5%)
Skin and subcutaneous tissue disorders	189 (9.1%)
Infections and infestations	75 (3.6%)
Respiratory, thoracic and mediastinal disorders	34 (1.6%)
Psychiatric disorders	27 (1.3%)
Vascular disorders	26 (1.3%)
Gastrointestinal disorders	24 (1.2%)
Blood and lymphatic system disorders	20 (1%)
Cardiac disorders	20 (1%)
Eye disorders	17 (0.8%)
Metabolism and nutrition disorders	15 (0.7%)
Musculoskeletal and connective tissue disorders	14 (0.7%)
Immune system disorders	11 (0.5%)
Investigations	9 (0.4%)
Surgical and medical procedures	9 (0.4%)
Congenital, familial and genetic disorders	2 (0.1%)
Hepatobiliary disorders	1 (0%)
Neoplasms benign, malignant and unspecified (incl cysts and polyps)	1 (0%)
Social circumstances	1 (0%)
Total Cases	2080

Compared to the previous PSUR period the SOC General disorders and administration site conditions raised from 20.5% to 32% in this PSUR and Injury, poisoning and procedural complications from 24.2% to 30.7% (two-fold increase of cases of inappropriate schedule of drug administration and wrong drug administered due to solicited interviews – see section on medication errors).

6.4. Manufacturer's Analysis of Individual Case Histories

As a company policy, all incoming adverse events are reviewed on an ongoing basis to detect any new safety signal. Once identified, all available data relating to the adverse events under review are routinely evaluated in a cumulative manner for a possible causal association with the suspect product.

The selection of the adverse events of interest as described in this section is based on the following criteria: reporting frequency, medical significance, severity of the events, mechanisms of action, issues that are being monitored, or requests by regulatory authorities.

The events of interest are described for all cases (irrespective of source, seriousness and listedness) within the PSUR review period. The events from the non-serious reports received solely from regulatory authorities are not included in the Line Listings and Summary Tabulations as per guideline E2C(R1). Separate Line Listings and Summary Tabulations are provided for consumer reports as per guideline E2C(R1). Therefore some reports may be reviewed and described in this section but will not appear in the line listing and summary tabulations of the PSUR.

The events are presented by MedDRA System Organ Classes (SOCs). Reports with a fatal outcome are discussed separately, regardless of the SOC of the primary AE is classified by MedDRA.

Where relevant, a company comment is provided.

6.4.1. Cases with a Fatal Outcome

A total of 14 cases with a fatal outcome were received during the reporting period. Narratives are presented in Appendix 5A. Note that non-medically verified reports are included. The narratives are produced directly from the safety database using a standard search strategy. The search strategy retrieves all cases in which the patient died or which are coded with MedDRA PTs indicating that death occurred. Thus the case narratives may include reports where the adverse event outcome is not specified as fatal in the line listings as well as reports of intra-uterine death or stillbirth.

CONFIDENTIAL

CONFIDENTIAL

The following fatal cases are considered as possible Sudden Death:

Case **B0601431A** - MedDRA Preferred Term: Sudden infant death syndrome

This case was reported by a healthcare professional and described the occurrence of cot death in a 3-month-old female who was vaccinated with the 2nd doses of Infanrix hexa™ and Prevenar on 21 October 2009. Two days after vaccinations, the subject died in bed. The parents found the baby lying on the belly. Autopsy did not reveal any cause of death.

Company comment: Suspected case of SIDS, autopsy did not reveal clear cause of death. No details on medical history available. The subject received concomitant vaccination with Prevenar.

Case **B0605003A** - MedDRA Preferred Terms: Cardiac arrest, Convulsion, Hypokinesia

This case was reported by the Italian regulatory authority and described the occurrence of cardiac arrest in a 2-month-old female who was vaccinated with an unspecified dose of Infanrix hexa™ on 10 August 2009. Less than one day after vaccination, the subject experienced convulsions. The subject was hospitalised from 14 August until 19 August 2009. At the time of reporting, the event was resolved with sequelae. Last convulsion episode was on 18 October 2009. The baby showed a regular growth but a light motor retardation in respect of the age. Her weight was 7.10 kg. Diagnostic tests as karyotype, ultrasonography, computerized axial tomography and nuclear magnetic resonance were negative. She was treated with Luminalette. According to the follow up information received on 01 June 2010, the subject died due to a cardiac arrest at an unspecified time after vaccination.

Company comment: Case of Sudden Unexpected Death in Infancy (SUDI). The subject had a history of convulsions since 2-months of age, which started less than one day after vaccination with Infanrix hexa™. The final diagnosis was not reported, however, the child received anticonvulsive treatment. Cause of death was reported as cardiac arrest, but circumstances of death were not available. It was unknown whether an autopsy was performed.

Case **B0608494A** - MedDRA Preferred Terms: Sudden infant death syndrome, Depressed level of consciousness, Mouth haemorrhage, Nasopharyngitis

This case was reported by a healthcare professional and described the occurrence of cot death in a 14-week-old male who was vaccinated with the 2nd dose of Infanrix hexa™ and Prevenar on 12 November 2009. The child was born at term and weighed 4120 g. The child had a history of viral infection before vaccination with the 1st dose of Infanrix hexa™ and Prevenar. In the beginning of November, 2 weeks before death, the subject had a common cold. The subject did not experience any adverse events after vaccination. Four days after vaccination with Infanrix hexa™ and Prevenar, the subject was brought to day care centre. He had no fever.

He burped well after being fed and was put into bed at 9:25 lying on the abdomen (with permission of the mother) and he was being checked every 20 minutes. At 12:00, the subject was nonresponsive and had blood in his mouth. Reanimation was started immediately and the child was admitted to hospital. The child died on 16 November 2009 from sudden infant death syndrome. An autopsy was performed and did not reveal any cause of death found in autopsy or on toxicological investigation.

Company comment: Possible case of SIDS. The subject had viral infections as medical history. No adverse events were reported after vaccinations. The subject was placed in prone position into bed. No clear cause of death was found on the autopsy.

Case **B0639243A** - MedDRA Preferred Terms: Sudden infant death syndrome, Asphyxia

This case was reported by a physician and described the occurrence of sudden infant death in a 7-week-old female four days after vaccination with unspecified doses of Rotarix and Infanrix hexa™. The reporter informed that the subject experienced suffocation during sleep.

Company comment: Case of SUDI or suspected SIDS. No medical history and circumstances of death were reported. The subject, according to the reporter, experienced asphyxia during sleep. It was unknown whether an autopsy was performed.

Case **B0657890A** - MedDRA Preferred Terms: Sudden infant death syndrome, Apnoeic attack, Pallor, Oxygen saturation decreased, Heart rate decreased

This case was reported by a healthcare professional and described the occurrence of sudden infant death syndrome in a 2-month-old male who was vaccinated with unspecified doses of Infanrix hexa™, RotaTeq and Prevenar on 27 April 2010. Concurrent medical condition included premature birth at 26 weeks of gestation. Twelve hours after vaccination, the subject went dusky and experienced apnoea attack, reduced oxygen saturation and decreased heart rate. The subject was hospitalised. Relevant test results included: heart rate more than 100 bpm, pO₂ over 94 %, normal cranial ultrasound and ophthalmological examination. The subject was treated with mechanical ventilation, stayed under observation for 48 hours and was discharged. Three days after discharge, the subject had another episode of apnoea and could not be resuscitated. The subject died from sudden infant death syndrome 5 days after vaccination.

Company comment: Case of SUDI. The subject died due to apnoea attack, likely related to his severe prematurity. It was unknown whether an autopsy was performed.

Case **D0064259A** - MedDRA Preferred Terms: Cardiac arrest, Sudden infant death syndrome, Sepsis, Viral infection, Resuscitation, Pyrexia, Loss of consciousness, Cyanosis

This case was reported by the German regulatory authority and described the occurrence of cardiovascular arrest in a 3-month-old male who was vaccinated with the 2nd dose of Infanrix hexa™ and Prevenar on 29 September 2009. The subject's parents have separated about two weeks prior to the events. The subject was cared for by the father with the help of his sister-in-law and mother-in-law. The subject did not experience any adverse event between date of vaccination and date of death. Approximately three days post-vaccination, in the morning around 07:30 the subject appeared normal. About half an hour later, at around 08:00, the subject was supposed to be fed with a bottle. The subject was found unconscious and the subject's body was blue (cyanosis). Upon arrival of an emergency physician the pupils were medium wide, no pulse could be determined and oxygen saturation could not be measured. The subject was intubated and cardiopulmonary resuscitation was started. Under ongoing resuscitation the subject was transferred to a hospital. In hospital the subject was treated with adrenaline and atropine. Echocardiography and ECG both showed no detectable heart reaction. Body temperature, taken in the ear, was 39.4 degC. Resuscitation was without success and was stopped. An autopsy was performed, but results were not conclusive. According to autopsy both SIDS and viral infection were possible causes of death. External force and shaken baby syndrome were excluded by autopsy.

Company comment: Case of SUDI. The subject died due to cardiac arrest 3 days after multiple vaccinations. The autopsy results were inconclusive and considered SIDS and viral infection as possible causes of death.

Case **D0064689A** - MedDRA Preferred Term: Sudden infant death syndrome

This case was reported by the German regulatory authority and described the occurrence of SIDS in 3-month-old male subject who was vaccinated with unspecified doses of Synflorix and Infanrix hexa™ on 04 November 2009. The subject has no underlying or concurrent medical conditions or other risk factors. The subject has received previous vaccination with Synflorix™ and Infanrix hexa™. It was unknown how previous vaccinations were tolerated. Approximately nine days post-vaccinations, the subject was found lifeless in bed in supine position covered by a cushion/pillow. An emergency physician was only able to certify death. Police reported that the children's room was severely overheated and in the whole apartment people had been smoking. Autopsy was performed and showed age-corresponding state of development and very good state of care. Multiple punctual haemorrhages up to the size of a pinhead were found under the thymus capsule, subepicardial and on the surface of the lungs. Distinct disorder of blood distribution was seen in the lungs as well as increased fluid and blood content in the lungs and foam in the respiratory tract (pulmonary edema). Neither signs of external force by a third party nor signs of shaken baby syndrome have been detected.

No signs of organic malformation have been detected. The cause of death could not be unambiguously determined. Punctual haemorrhages under the thymus capsule, subepicardial and on the surface of the lungs were normally seen within the scope of SIDS and therefore the autopsy performing physicians considered SIDS. Possible risk factors associated with SIDS included coverage with a pillow, severely overheating, not feeding with breast milk and passive smoking. Furthermore autopsy showed increased water retention of the lungs as well as distinct disorder of blood distribution within the lungs, which could be signs of a beginning pulmonary infection. Microbiological examinations, performed on 20 November 2009, showed solitary *St. aureus* in both pulmonary swabs and a single *St. aureus* colony in the spleen swab as potential infectious agent, but this bacterium was also known as normal bacterial flora of the upper respiratory tract. All other bacteria found belong either to physiological intestinal flora or were normal parts of the throat and skin flora. Therefore infectious events could be excluded with some probability.

Company comment: Case of SUDI. The subject died 9 days after multiple vaccinations. The autopsy results were inconclusive and considered SIDS (in presence of numerous risk factors) and pulmonary infection as possible causes of death.

Case **D0065445A** - MedDRA Preferred Term: Sudden infant death syndrome

This case was reported by a physician and described the occurrence of SIDS in a 3-month-old female one day after vaccination with the 1st dose of Infanrix hexa™ and Prevenar on 09 December 2009. The subject's development and weight gain were normal, her medical history was unsuspecting. She was breast-fed for three months. Post-vaccinations the subject did not experience fever. Next morning after vaccinations, the subject was normally drinking and was put in bed. Approximately two to three hours later, the subject was found lifeless in bed in supine position. The subject died on 10 December 2009 from SIDS. An autopsy was performed, but no results were available.

Company comment: Suspected case of SIDS. The subject died 1 day after multiple vaccinations. Subject's medical history was unsuspecting, no adverse event were reported after vaccinations. Autopsy was performed, but the results were not available.

Case **D0066068A** - MedDRA Preferred Term: Sudden infant death syndrome

This case was reported by a physician and described the occurrence of possible SIDS in a 3-month-old male who was vaccinated with unspecified doses of Infanrix hexa™ and Prevenar on 29 December 2009. The subject had three healthy siblings. He was a healthy term baby and was breast-fed. The subject's mother did not smoke. The subject had received the last meal, consisting of mother's milk on 29 December 2009 in the evening. Later on in the evening, the subject was found dead under unknown circumstances in bed. An autopsy was performed. The results of autopsy were inconclusive and showed no obvious cause of death. Therefore cause of death was considered to be SIDS.

Company comment: Possible case of SIDS. The subject died less than 1 day after multiple vaccinations. Subject's medical history included healthy term baby, without underlying condition. Autopsy did not reveal clear cause of death.

Case **D0067790A** - MedDRA Preferred Terms: Sudden infant death syndrome, Death, Apnoea, Cardiac arrest, Loss of consciousness, Resuscitation

This case was reported by the German regulatory authority and described the occurrence of SIDS in a 9-week-old male who was vaccinated with Infanrix hexa™ and Prevenar on 31 March 2010. Complication during pregnancy included cranial haemorrhage of the mother due to cerebral artery aneurysm in the 19th week of gestation. The subject was born in the 33rd week of pregnancy by Caesarean section. At that time the subject was immature with a birth weight of 1805g with mild respiratory distress syndrome. Postnatal the subject showed good adaptation, but chest X-ray, performed on 28 January 2010, showed mixed picture of mild neonatal respiratory distress syndrome and wet lung. Repeated sonography and neonatal screening were normal. Concurrent medications included colecalciferol and iron salt. For the third child health check, performed on 04 March 2010, the subject showed normal development concerning weight, length and head circumference. The subject showed no pathologic findings except mild hydrocele. However, according to percentile curve of the WHO the subject was in reduced nutritional condition with a weight of 3700g and a height of 55cm. Approximately 3 days after vaccinations in the morning the subject experienced apnoea. When the emergency care team arrived the subject was unconscious. Cardiac arrest with apnoea and asystole was diagnosed. Resuscitation was unsuccessful. Concurrent medical conditions included old contusion and hematoma on right side of chest. An autopsy was performed and macroscopically, did not reveal unambiguous cause of death. All autopsy findings were suggestive for SIDS. The findings not consistent with SIDS (skin fissures in the corner of mouth, ecchymoses in area of central chest wall, hemorrhage in capsule of adrenal gland and kidney) can be explained with plausibility by long and continuous resuscitation. Further toxicological examination could not identify the cause of death. According to the report on the histological examination, results largely confirmed the findings of the autopsy.

Besides unspecific signs of death, punctuate haemorrhage of the organs' connective tissue coatings and pulmonary emphysema were considered the essential findings. Acute emphysema could be interpreted as evidence of suffocation. It was concluded that definite cause of death could be identified, neither in histological examinations nor in toxicological tests. It was discussed that the toxicological tests covered a certain spectrum of substances only and would miss some rare and exceptional substances. Because of the combination of pulmonary emphysema and the fissures at the left corner of the mouth, which had been observed during the autopsy, death due to suffocation following violent obstruction of respiratory orifices could not be excluded. Likewise it could not be excluded that these findings were caused during the reanimation procedures.

Company comment: Case of SUDI. Preterm subject, with respiratory distress in medical history, died approximately 3 days after multiple vaccinations. Autopsy did not reveal clear cause of death. Majority of findings were within SIDS, however violent obstruction of respiratory tract could not be excluded.

The following fatal cases were significantly confounded by concomitant disease and/or medication and/or vaccination and are not suggestive of sudden death:

Case **B0661542A** - MedDRA Preferred Terms: Metabolic disorder, Ataxia, Balance disorder, Diplopia, Strabismus, Nervous system disorder

This case was reported by a physician and described the occurrence of ataxia in a 6-month-old male who was vaccinated with the 3rd doses of Infanrix hexa™ and Prevenar in March 2010. The subject's medical history included episodes of shaking head, arms and legs several times a day, which occurred at the age of 5 months. Five days after vaccinations, the subject experienced ataxia, instability and diplopia (described as strabismus). The physician suspected a possible neurological alteration. The subject was hospitalized and some relevant tests (NMR, ECG, CSF, other unspecified laboratory tests, nasopharyngeal exudates) were performed and showed normal results. Catecholamine and muscular biopsy results were pending. The ataxia remained until the age of 9 months. The shaking moves have repeated in some occasions. The subject was hospitalized in an intensive care due to a possible aspiration from 16 to 24 June 2010. He underwent EEG in July 2010 and it showed 3 lesions compatible with metabolic disorder. The final diagnosis was a possible metabolic disease with very limited clinical picture. According to the follow-up information received in August 2010, the subject died in July 2010 due to a possible metabolic disorder of a mitochondrial origin.

Company comment: The subject died due to a possible metabolic disorder of a mitochondrial origin several months after 3d vaccination with Infanrix hexa™ and Prevenar. It was unknown whether an autopsy was performed.

The following cases were considered too poorly documented to allow for an appropriate medical assessment:

Case **B0599802A**- MedDRA Preferred Term: Death, Adverse drug reaction

This case was reported by a healthcare professional and described the occurrence of death NOS (not otherwise specified) in a 4-month-old female who was vaccinated with the 3rd dose of Infanrix hexa™ and Prevenar on 15 October 2009. Eleven days after vaccination the subject experienced death NOS. The subject experienced adverse drug reaction and was found dead in her bed after her afternoon nap. The subject had no concomitant medication and no relevant medical history. The subject was transferred to hospital. Hospital report was pending. No autopsy was performed. Follow-up information has been requested.

Case **D0063296A** - MedDRA Preferred Term: Death

This case was reported by the German regulatory authority and described the occurrence of death in a 12-week-old male who was vaccinated with unspecified doses of Infanrix hexa™ and Prevenar on 9 January 2006. The subject's mother suffered from epilepsy. The subject was exposed in utero to levetiracetam during about the first three months of pregnancy. The rest of pregnancy and birth was inconspicuous, except for fracture of a clavicle. Concurrent medical conditions included agitation and crying abnormal (whiny baby). Approximately 11 days post-vaccination, the subject died. The cause of death was not further specified. It was unknown whether an autopsy was performed.

Case **D0069211A** - MedDRA Preferred Term: Death

This case was reported by a physician and described the occurrence of unspecified death in a child of unspecified gender who was vaccinated on an unspecified date with an unspecified 6-valent vaccine and unspecified pneumococcal vaccine (manufacturers unspecified). One day after vaccinations, the subject was hospitalised to a paediatric intensive care unit and reanimated, but died from unknown cause. An autopsy was performed. Follow-up information has been requested.

6.4.2. Other adverse event of interest

6.4.2.1. Blood and lymphatic system disorders

6.4.2.1.1. Idiopathic thrombocytopenic purpura, Thrombocytopenia, Thrombocytopenic purpura

Eleven serious cases including the event idiopathic thrombocytopenic purpura (n=6), thrombocytopenia (n=6) or thrombocytopenic purpura (n=1) were received during the period of this PSUR and are described below.

Case **B0615557A**- MedDRA Preferred Term: Thrombocytopenia

This case was reported by the Italian regulatory authority and described the occurrence of thrombocytopenia in a 5-month-old male who was vaccinated with Infanrix hexa™. No information was provided regarding medical history. On 14 October 2009 the subject received the 2nd dose of Infanrix hexa™. On 5 November 2009, 22 days after vaccination, the subject experienced thrombocytopenia. The subject was hospitalised. At the time of reporting the outcome of the event was unspecified.

Company comment: The symptoms and signs leading to this diagnosis in a 5 month-old-baby were not reported. No results of any diagnostic tests to exclude other causes of thrombocytopenia were reported.

CONFIDENTIAL

CONFIDENTIAL

Case **B0619820A**- MedDRA Preferred Terms: Idiopathic thrombocytopenic purpura, Haematoma, Rectal haemorrhage, Purpura

This case was reported by a physician and described the occurrence of purpuric spots in a 3-month-old male who was vaccinated with Infanrix hexa™ and Prevenar. Past vaccinal history included a first injection of Infanrix quinta at an unspecified date, without problem. The subject had no past medical history of purpuric spots. On 04 December 2009, the subject received a 2nd dose of Infanrix hexa™ and an unspecified primary dose of Prevenar. In the evening the subject presented with several purpuric spots on the body (not specifically on lower limbs). At an unspecified date, the subject developed small hematomas. On 21 December 2009, new purpuric spots had appeared on trunk, anal area, neck and nape of the neck. Events included also rectal haemorrhage. The subject was hospitalised and a diagnosis of idiopathic thrombocytopenic purpura was made. Platelet count showed thrombocytopenia. He was treated with immunoglobulin which was inefficient. He was then given a transfusion on unspecified date and events resolved. On 03 March 2010, the subject received a third dose of Infanrix quinta, without recurrence of the events.

Company comment: No data confirming immunological cause of the event was provided. Detailed diagnostic tests are lacking. On the basis of the information provided, the time to onset appears to be rather short. Immunoglobulin therapy was inefficient and subject recovered only after blood transfusion. Negative re-challenge after 3d dose of Infanrix quinta.

Case **B0630988A**- MedDRA Preferred Terms: Thrombocytopenic purpura, Viral infection, Pyrexia, Rash, Petechiae, Ecchymosis

This case was reported by the Italian regulatory authority and described the occurrence of thrombocytopenic purpura in a 12-month-old female after vaccination with a 3rd dose of Infanrix hexa™ and unspecified dose of MMR II (non-GSK). Previous vaccinations were well tolerated. Fifteen days after vaccination with Infanrix hexa™ and MMR II and a few days after a viral infection (with fever and exanthema), the subject was hospitalized on 30 June 2007 with petechia and ecchymosis. Platelet count gradually rose on 30 June 2007: 4000; on 2 July 2007: 8800; on 5 July 2007: 13500; on 13 July 2007: 17500 and on 20 August 2007: 161000. The subject was diagnosed with thrombocytopenic purpura and was treated with prednisone.

Company comment: The event was observed 15 days after multiple vaccinations and a few days after onset of an acute viral illness.

Case **B0652855A** - MedDRA Preferred Terms: Purpura, Petechiae, Thrombocytopenia

This case was reported by the French regulatory authority and described the occurrence of purpura in a two-month-old female who was vaccinated with Rotarix, Infanrix hexa™ and Prevenar. During the ninth month of pregnancy, her mother received an unspecified dose of swine flu H1N1 vaccine (unknown manufacturer). On 03 February 2010, the subject received an unspecified dose of BCG vaccine (non-gsk). On 01 March 2010, the subject was vaccinated with an unspecified dose of Rotarix, Infanrix hexa™ and Prevenar. Six days after vaccination, the subject developed purpura and petechia around mouth and then, on hands and feet. On 08 March 2010, petechia had extended to the abdomen. The subject had no fever. On 10 March 2010, the subject was hospitalised. Blood work-up showed WBC at 5.5 G/L with neutrophils at 2.5 G/L, Hb 9.2 g/dL, platelets count at 4 G/L (thrombocytopenia), C-reactive protein at 1 mg/L, normal value of liver enzymes. Viral serologies were negative for EBV, CMV and Toxoplasma and positive for Parvovirus (Parvovirus B19 serology). Coombs test was negative. The subject was treated with normal immunoglobulin. On 11 March 2010, platelet count was at 47 G/L.

The purpura and petechia resolved within an unspecified period of time. Outcome of thrombocytopenia was unspecified.

Company comment: This two-month-old female experienced thrombocytopenia 6 days after multiple vaccinations. Positive serology test to Parvovirus infection provides a plausible alternative explanation for the reported events.

Case **B0656703A**- MedDRA Preferred Terms: Idiopathic thrombocytopenic purpura, Petechiae, Abnormal behaviour, Purpura

This case was reported by the French regulatory authority and described the occurrence of idiopathic thrombopenic purpura in a 2-month-old male who was vaccinated on 19 March 2010 with unspecified doses of Infanrix hexa™ and Prevenar. Medical conditions were unspecified. On 27 March 2010, eight days after vaccinations, the subject presented with disturbed behavior and purpuric rash which generalized on 28 March 2010, without fever. On 28 March 2010, the subject was hospitalized. Full blood count showed platelet at 14000/mm³, Hb at 12.6 g/dl and WBC 12270/mm³. Treatment with cefotaxime and vancomycine was started. The subject was transferred in another hospital. Physical examination showed petechiae on soft palate and tongue and purpuric spots all over the body. Lab tests showed platelet lower than 10000/mm³ and reticulocytes at 57200/mm³. Coombs test was negative. Cerebral CT scan and thorax X-ray were normal. On 28 and 30 March 2010, normal immunoglobulin was administered at 0.8 g/kg. Clinical course was favourable with platelet at 136000/mm³ on 31 March 2010. The reporter concluded to an idiopathic thrombopenic purpura. At the time of reporting, the events were resolved without sequelae.

Company comment: Medical conditions were not reported. The narrative did not exclude recent infection, based on increase value of WBC, which may be a trigger of the event. Coombs test was negative.

Case **B0665357A**- MedDRA Preferred Term: Thrombocytopenia

This case was reported by the Italian regulatory authority and described the occurrence of thrombocytopenia in a male subject of unspecified age who was vaccinated at an unspecified date with an unspecified dose of Infanrix hexa™. The subject was hospitalised. At the time of reporting, the outcome of the event was unspecified.

Company comment: This report lacks important information for medical assessment.

Case **D0066805A**- MedDRA Preferred Terms: Idiopathic thrombocytopenic purpura, Haematoma, Petechiae, Mouth haemorrhage

This case was reported by a physician and described the occurrence of idiopathic thrombocytopenic purpura in a 12-month-old female who was vaccinated with Priorix™ Tetra and Infanrix hexa™. The subject's medical history included influenza-like infection one week prior to vaccination. The subject had no relevant underlying or concurrent medical conditions and received no concomitant medication. Former vaccinations with Infanrix hexa™ in February 2009, March 2009 and April 2009 were well tolerated. On 27 November 2009 the subject received the 1st dose of Priorix™ Tetra and the 4th dose of Infanrix hexa™. On 16 December 2009, 19 days after vaccination with Infanrix hexa™ and Priorix™ Tetra, the subject experienced ITP. Diagnosis was based on laboratory test (haemogram). The subject was hospitalised from 20 December 2009 to 28 December 2009 due to suspected chronic idiopathic thrombocytopenia. At admission the subject was in good general conditions, nutritional status normal, petechiae on neck to left shoulder and on the top of the head fronto-temporal (left side), multiple hematoma different in size and age on legs and sporadic on arms, one hematoma on bottom (right side), small petechiae on roof of mouth - soft palate. Other physical and neurological examinations were without findings. Blood tests showed slight signs of anaemia and infection. In the course of hospital stay remission of petechiae with gradual increase of thrombocytes was achieved. During check-up after hospital discharge there was only a minimal increase of thrombocytes up to 30000. A sonography performed on 20 January 2010 was normal. The duration of ITP was two weeks. Required treatment did not include blood transfusion, platelet transfusion, gamma globulin, and corticosteroid.

Company comment: This 12-month-old female experienced ITP 19 days after administration of the 4th dose of Infanrix hexa™ and the 1st dose of Priorix tetra. The subject's influenza-like infection one week before may be considered as a plausible alternative explanation for the reported events. The purpura resolved, but thrombocytopenia persisted after hospital discharge. No tests confirming immunological cause of ITP were provided.

Case **D0067175A**- MedDRA Preferred Terms: Idiopathic thrombocytopenic purpura, Thrombocytopenia, Petechiae

This case was reported by the German regulatory authority and described the occurrence of idiopathic thrombocytopenic purpura in a 4-month-old female who was vaccinated with Infanrix hexa™ and Prevenar. There was no concurrent medical condition. On 28 July 2009 the subject received 1st dose of Infanrix hexa™ and Prevenar. On 28 August 2009, 31 days after vaccinations, the subject experienced ITP and thrombocytopenia (platelet count was 4000/mcl). The subject was hospitalised for further diagnostics because of increasing petechiae. After discharge from hospital beginning of September 2009, the subject visited the hospital for regular follow ups. Platelet count was normalizing quickly. After 8 weeks, in October 2009, the events were resolved spontaneously. After the 2nd vaccination with Infanrix hexa™ and Prevenar on 4 November 2009, the events did not recur.

Company comment: This 4-month-old female subject experienced ITP 31 days after administration of multiple vaccines. The case lacks data to confirm immunological cause of the event. No treatment provided in a hospital and results of laboratory tests were reported. Negative re-challenge after the 2d doses.

Case **D0067177A** - MedDRA Preferred Terms: Thrombocytopenia, Idiopathic thrombocytopenic purpura, Gastroenteritis, Petechiae, Haematoma, Vomiting, Diarrhoea, Injection site inflammation, Injection site induration, Incorrect route of drug administration

This case was reported by the German regulatory authority and described the occurrence of thrombocytopenia in a 15-month-old female who was vaccinated with Priorix Tetra, Infanrix hexa™ and Prevenar. Previous 3 vaccinations with Infanrix hexa™ and Prevenar on 7 April, 14 May and 5 July 2009 were well tolerated. On 29 January 2010 the subject received 1st dose of Priorix. The subject's medical history included premature baby. Concurrent medications included Iron salt. Previous medications included Paracetamol a few days before start of the events.

On 25 February 2010 the subject received the 4th doses of Infanrix hexa™ (right thigh) and Prevenar (left thigh). On 25 February 2010, less than one day after vaccinations, the subject experienced livid injection site inflammation and injection site induration (3 x 5 cm) on the left thigh. On 25 February 2010, a blood sample was taken because of a ferrum therapy. This blood sample showed thrombocytopenia of 25 G/l. The parents did not see any petechiae or hematoma. The subject was hospitalised. On admission examination, the subject was in good general condition. There were solitary petechiae and 2 small hematomas on right knee. ITP was diagnosed. The subject did not receive therapy for thrombocytopenia.

During hospital stay, since 04 March 2010 the subject experienced gastroenteritis with recurrent vomiting and watery stools. The subject was treated with parenteral hydration. After gastroenteritis was improved, thrombocyte count increased (34 G/l), the subject left the hospital in good general condition. At the time of reporting the outcome of ITP, injection site inflammation, injection site induration, petechiae and hematoma was unspecified. It was reported that the last blood test in March 2010 showed normal platelet count.

Company comment: Events occurred on the same day as of vaccination with Infanrix hexa™ and Prevenar. There were no symptoms of bleeding, and the thrombocytopenia was diagnosed on blood test. Reported time to onset of less than 1 day is rather short. Underlying iron therapy suggests anaemia of unspecified genesis. It was reported that no specific therapy was prescribed and thrombocytopenia resolved spontaneously. .

Case **D0068471A** - MedDRA Preferred Terms: Idiopathic thrombocytopenic purpura, Petechiae, Haematoma, Hypochromic anaemia, Upper respiratory tract infection, Rhinitis, Pyrexia, Constipation

This case was reported by the German regulatory authority and described the occurrence of ITP in an 8-month-old male who was vaccinated with Infanrix-IPV/Hib, Infanrix hexa™ and Prevenar. Concurrent medical conditions included constipation and rhinitis. On 03 July 2008 and 28 August 2008 the subject received the 2 dose of Infanrix hexa™ and Prevenar. Vaccinations have been well tolerated. On 10 November 2008 the subject received a dose of Infanrix-IPV/Hib and developed 25 days later, on 05 December 2008, ITP. Thrombotic thrombocytopenic purpura, leukaemia, von Willebrand syndrome and infection were excluded. Diagnosis of ITP was supported by results of blood counts and bone marrow puncture. The subject was hospitalized because of hematoma and petechiae. The subject was treated with a single dose of intravenous immunoglobulin. Thrombocytes count increased to 49 000 cells/mcl. Then thrombocytes went down to 14000 cells/mcl again, and the subject was hospitalized again. A few days prior to this hospitalization the subject had developed rhinitis. At the time of hospitalization, mild hematoma was observed on the subject's forehead. The subject was treated with intravenous immunoglobulin and thrombocyte count increased to 72000cells/mcl. Hypochromic microcytic anemia was evident in lab results on 12 December 2008. Subsequently the subject was treated with steroids. The subject was hospitalized again between 08 and 09 February 2009 because of fever and upper respiratory tract infection which started on 06 February 2009. Diagnosis also included ITP and chronic constipation. At the time of hospitalization the subject had hematoma and petechiae. The subject's thrombocytes were 25 000 cells/mcl on 08 February 2009 and 54000 cells/mcl on 09February 2009. The subject was treated with Metamizol. Beginning of April 2010, thrombocytes count showed 60000 cells/mcl. Fourteen days later, on 27 April 2010, the subject developed again haematomas, which was diagnosed as relapsing ITP. During further course, thrombocyte count decreased to 10000 cells/mcl, but the subject had minor haematoma and petechiae. Concurrent immune defect was excluded. Lymphocyte sub-typing on 13 May 2010 showed normal result except of mildly decreased B-lymphocytes cell count, weakened antibody-dependent cell-mediated cytotoxicity and decreased cell count of natural killer cells. Since 03 June 2010, the subject was treated with mycophenolate mofetil (CellCept) for immune suppression, which was well tolerated. Thrombocyte count increased slowly (up to 87000/mcl on 01 July 2010). Due to again decreased thrombocyte counts (22000/mcl), subject's mother decided to discontinue treatment with CellCept on 17 July 2010. On 21 July 2010, the subject went to see the doctor. He had no haematomas and no petechiae. His state in general was uneventful.

Company comment: The subject experienced a first episode of chronic ITP 25 days after dose of Infanrix-IPV/Hib vaccine. No immune cause of this event was confirmed. No clear triggers of further episodes were reported.

Case **D0069059A** - MedDRA Preferred Terms: Warm type haemolytic anaemia, Thrombocytopenia, Jugular vein thrombosis, Jaundice acholuric, Incorrect route of drug administration

This case was reported by a consumer via the German regulatory authority and described the occurrence of warm type hemolytic anemia in a 4-month-old male 5 days after vaccination on 5 August 2010 with the 1st dose of Infanrix hexa™ and Prevenar. The subject was hospitalised from 10 to 21 August 2010 and from 29 August to 29 September 2010. Another dose of both vaccines was administered at an unspecified date. According to the hospital report from second hospitalisation, the subject's medical history included neonatal jaundice in the first six days of life. No haemolytic or congenital diseases were known in the family. The grandmother lost two infants within the first year of life, but the cause of death was unknown. The subject had an upper airway infection approximately four weeks prior to hospitalisation. When admitted, the subject showed scleral jaundice, skin jaundice, firm liver was palpable 4 cm below rib bow, spleen palpable adjacent. Blood tests showed low values of haemoglobin and RBC, high bilirubin and reticulocyte counts and a normal platelet count. The subject was diagnosed with autoimmune haemolytic anaemia, haemolytic jaundice, thrombocytopenia with suspect immune thrombocytopenia and jugular vein thrombosis at the right. The subject was first hospitalised to an intensive care unit. Because of distinct anaemia and haemolysis, the subject was treated with red blood cells. Autoimmune antibodies of warm type could be detected as a cause of haemolysis. Treatment with prednisolone was without success, with high haemolysis parameters and transfusion in further course. Because additional development of immune thrombocytopenia was suspected, treatment with immunoglobulin was started, but the effect was lasting only a short time. Finally treatment with rituximab was started, which was well tolerated. Haemolysis parameters normalised and haemoglobin value stabilised at 8.1 g/dl.

Company comment: Subject developed haemolytic anaemia 5 days after vaccination with the 1st dose of Infanrix hexa™ and Prevenar. The subject had neonatal jaundice at birth and a respiratory infection approximately 3 weeks before vaccinations. Warm type haemolytic anaemia was diagnosed, but no laboratory tests were provided. Immune thrombocytopenia was suspected, however platelets count was normal.

6.4.2.1.2. Warm type haemolytic anaemia

One serious case was reported with the PT „warm type haemolytic anaemia“.

This case (**D0069059A**) is described in section [6.4.2.1.1](#) on thrombocytopenia.

6.4.2.2. Cardiac disorders

6.4.2.2.1. Cyanosis

Fifty cases including the event cyanosis were identified during the period of this report.

Most cases (45/50) were reported in association with a concurrent disease likely to have caused cyanosis, as shown in Table 5. Only 1 concurrent disease is shown per case, however more than 1 relevant concurrent disease may have been reported for a given case.

Table 5 Concurrent diseases reported in 44 cyanosis cases identified during the period of this PSUR

Concurrent disease	Case IDs
Seizures (n=13)	B0604826A; B0629094A; B0641899A; B0669299A; B0670625A; B0676877A; B0677130A; D0066414A; D0067732A; D0068664A; D0068927A; D0069021A; D0069116A
HHE (n=4)	B0632568A; B0661768A; B0668109A; B0677571A
Hypotonia (n=14)	B0604992A; B0614414A; B0614538A; B0629247A; B0636914A; B0641793A; B0643302A; B0645116A; B0647347A; B0649654A; B0651462A; B0657507A; B0657949A; D0068505A
Hypertonia (n=1)	B0675492A

ALTE (n=1)	D0064655B
(Pre)Syncope (n=2)	B0656982A; B0679695A
SIDS (n=1)	D0064259A (described in section 6.4.1)

Of the 5 remaining cases:

Case **B0639439A** reported restlessness, crying uncontrollably, leukocytosis, cyanosis and injection site reaction occurring less than 1 day after vaccination in a 1-month-old male. Blood smear showed increased leukocytosis with deviation to the right. At the time of reporting, the events were resolved.

Case **B0642862A** reported perioral cyanosis and cyanosis on both-legs and on vulva in a 2-month-old female on the same day as vaccination with Infanrix hexa™ and Prevenar. Subject was treated with Paracetamol. Events resolved.

Case **B0651924A** reported cyanosis and fever (38 degC) in a 3-month-old male who was vaccinated with Infanrix hexa™ and Prevenar. EEG was negative. The subject was treated with paracetamol. At the time of reporting, the events were resolved.

Case **B0675235A** reported cyanosis with discomfort, emotional distress, erythema and screaming in a 2-month-old female on the same day as vaccination with unspecified doses of Infanrix hexa™ and Prevenar. The subject was treated with paracetamol (Calpol). The events resolved on the same day.

Case **B0677866A** reported persistent inconsolable crying associated with mottled skin, cyanosis and tachycardia in a 4-month-old male a few hours with Infanrix hexa™ and Prevenar. The subject was hospitalised and treated with Saccharose, paracetamol (Doliprane) and codeine phosphate (Codenfam). Events subsequently slowly improved.

6.4.2.3. Eye disorders

6.4.2.3.1. Gaze palsy

During the reporting period 24 cases of gaze palsy, all serious, have been received.

It concerned 15 males and 9 females, aged between 1 month and 2 years (median: 5.5 months). Time to onset ranged between less than 1 day to 7 days (median: less than 1 day). Outcome was reported as resolved in 19 cases, unresolved in 1 case and unknown at time of reporting in 4 cases.

Table 6 summarises cases of gaze palsy. Cases with bolded event terms are also analysed/summarised in the relevant sub-sections of section 6.4 of this PSUR.

CONFIDENTIAL

CONFIDENTIAL

Table 6 Overview of cases of gaze palsy

Case ID	Age	Gender	Events PT Comma Sep	Suspect Drugs PT Comma Sep	Concurrent Drugs PT Comma Sep	Time To Onset Since Last Dose	Case Outcome
B0599801A	2 Months	Male	Depressed level of consciousness, Crying, Hyperhidrosis, Vasodilatation, Gaze palsy, Pyrexia, Inflammation	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		3 Seconds	Resolved
B0613669A	2 Months	Male	Infantile spasms , Gaze palsy, Muscle spasms, Sleep disorder, Condition aggravated, Motor dysfunction, Hypertonia	Infanrix-polio-HIB, Infanrix hexa		1 Weeks	Resolved
B0614538A	2 Months	Male	Respiration abnormal, Gaze palsy, Loss of consciousness, Pallor, Cyanosis , Hypotonia	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		5 Hours	Resolved
B0642185A	15 Months	Female	Altered state of consciousness, Gaze palsy, Tonic convulsion, Convulsion, Epilepsy , Gastroenteritis, Febrile convulsion , Hypertonia, Ear infection, Gastritis, Nasopharyngitis, Hypotonia, Body temperature increased, Vomiting, Diarrhoea, Pyrexia	Infanrix hexa, Pneumococcal vaccines (Non-GSK)		5 Days	Unknown

6.4.2.3.2. Retinal haemorrhage

During the period of this report, two cases of retinal haemorrhage were received.

In case **B0677766A** the event was reported in the context of status epilepticus. This case is described in section 6.4.2.8.3 on seizures.

Case **B0636708A** - MedDRA Preferred Terms: Anaemia, Apnoea, Metabolic acidosis, Retinal haemorrhage, Child maltreatment syndrome

This case was reported by the Italian regulatory authority and described the occurrence of anaemia in a 3-month-old female who was vaccinated with unspecified dose of *Infanrix hexa*TM and *Prevenar*. On 3 July 2009, less than one day after vaccination, the subject experienced anaemia, apnoea, metabolic acidosis, retinal bleeding. The reporter suspected a shaken baby syndrome. The subject was hospitalised. At the time of reporting the events were resolved.

Company comment: The symptoms and tests results confirming the diagnosis of retinal haemorrhage were not reported. Child maltreatment syndrome was suspected. The event resolved.

6.4.2.4. Gastrointestinal disorders

6.4.2.4.1. *Diarrhoea haemorrhagic, Haematochezia, Melaena, Rectal haemorrhage*

During the period of this report, 10 cases were received with one the following MedDRA Preferred Terms: diarrhoea haemorrhagic (n=1), haematochezia (n=7), melaena (n=1) and/or rectal haemorrhage (n=3).

In case **B0619820A** rectal haemorrhage was reported together with idiopathic thrombocytopenic purpura. This case is described in section 6.4.2.1.1 on idiopathic thrombocytopenic purpura.

In case **B0643201A** haematochezia was reported in association with intussusception, this case is summarised in section 6.4.2.4.2 on intussusception.

In case **B0651961A** diarrhoea haemorrhagic and rectal haemorrhage were reported in association with intussusception, this case is summarised in section 6.4.2.4.2 on intussusception.

In case **B0663295A** haematochezia was reported together with anaphylactic reaction. This case is described in section 6.4.2.5.1 on anaphylactic reaction.

The other cases are summarised below.

Case **B0605572A** - MedDRA Preferred Term: Haematochezia

This case was reported by a physician and described the occurrence of blood in stools in a 2-month-old male. In August 2009 and October 2009, the subject received the 1st and 2nd doses of Rotarix and Infanrix hexa™. Two to 3 days after each vaccination, the subject experienced blood in stools. Since onset of the event until the time of reporting, the subject was under non-dairy diet to exclude food allergy. The event lasted 2 to 3 days.

Company comment: Intermittent episodes of bloody stool occurred after multiple vaccinations. No medical history and diagnostic tests results were provided. No type of bleeding and other symptoms were reported

Case **B0615474A** - MedDRA Preferred Terms: Haematochezia, Diarrhoea, Pyrexia

This case was reported by a physician and described the occurrence of bloody mucus in stool in a 3-month-old male who was vaccinated with Infanrix hexa™. The subject did not have history of blood in stools. Medical condition included a possible acute gastroenteritis. In September 2009, the subject received a dose of BCG vaccine. In October 2009, the subject received a first dose of Infanrix hexa™ and a first dose of Prevenar. First dose of Infanrix hexa™ was well tolerated. On 13 November 2009 the subject received the 2nd dose of Infanrix hexa™. On the evening, the subject experienced fever at 38 deg C, which was treated with paracetamol.

On 14 November 2009, he presented with mild soft and bloody mucous stool which lasted five days. The subject was seen in an emergency service. Stool culture performed on the same day was negative. On that same day, fever was resolved. In December 2009, physical examination was normal. The physician considered soft and bloody mucous stool as possibly related to an acute gastroenteritis episode.

Company comment: A 3-month-old male subject experienced the event one day after vaccination with Infanrix hexa™. Acute gastroenteritis was suspected, but no details on symptoms, physical examination, investigations and treatment were reported.

Case **D0068600A** - MedDRA Preferred Terms: Haematochezia, Mucous stools, Faeces discoloured, Crying

This case was reported by the German regulatory authority and described the occurrence of bloody stools in a 3-month-old male subject who was vaccinated with the 2nd doses of Infanrix hexa™ and Synflorix™. The subject has no underlying or concurrent medical conditions or other risk factors. Less than one day post-vaccination the subject was weepy and experienced yellow coloured stool which contained mucus and was blood-tinged (bloody stools) for about two days. The subject was not hospitalised for the events. Blood count, blood coagulation parameters and ultrasound scan were normal. After about two days, on 02 September 2009, the events were resolved.

Company comment: A 3-month-old male subject experienced bloody stools on the same day as of multiple vaccinations. All investigations were normal. The event resolved spontaneously, no treatment reported.

Case **D0068909A** - MedDRA Preferred Terms: Haematochezia, Crying, Mucous stools, Restlessness,

This case was reported by a physician and described the occurrence of blood in stools as well as crying episodes in a nearly 4-month-old female less than one day after vaccination with the 2nd doses of Rotarix™, Infanrix hexa™ and Prevenar. First dose of Rotarix™ was well tolerated. The subject was examined ambulatory in a hospital. The subject had mucus and blood in stool. She was restless and treated with paracetamol. The following day the amount of blood increased, the subject was eating less, but was calm. She had no diarrhea, fever, vomiting, constipation or hard stool and no rhinitis or cough. Clinical examination was normal, without exanthema, petechiae or hematoma. Digital rectal examination showed no blood. Blood test including coagulation and stool test for pathologic germs was without pathologic findings: negative in culture for Salmonella, Shigella, Yersinia, Campylobacter, Staphylococcus, negative for dyspepsia coli including EPEC (culture + agglutination), Campylobacter antigen. Sonogram of abdomen showed no invagination, but meteorically enlarged intestine. No treatment was necessary. Blood in stool was resolved 4 days after the onset, the other events resolved on an unspecified date.

Company comment: A 4-month-old male subject experienced bloody stools on the same day as of multiple vaccinations. The event resolved spontaneously and did not required treatment.

Case **B0671786A**- MedDRA Preferred Terms: Rectal haemorrhage, Abdominal pain, Haematochezia

This case was reported by a physician and described the occurrence of rectal bleeding in a 2-month-old female who was vaccinated with the 1st dose of Infanrix hexa™ and unspecified dose of Prevenar. Two days after vaccinations, the subject experienced colic and rectal bleeding. About 2 weeks after vaccination, the subject experienced bloody stools and rectal bleeding. The subject was hospitalised. Colic and rectal bleeding resolved (lasted for 2 weeks).

Company comment: Rectal haemorrhage and haematochezia occurred 2 days after multiple vaccinations. Medical history, results of any investigations, treatment and outcome are unknown.

Case **B0624719A** - MedDRA Preferred Terms: Melaena, Oesophagitis, Pyrexia, Vomiting, Irritability

This case was reported by the Italian regulatory authority and described the occurrence of melaena, oesophagitis, fever, vomiting and irritability in a 2-month-old male on the same day as vaccination on 8 October 2007 with an unspecified dose of Infanrix hexa™. The events were reported as resolved in 5 months.

Company comment: The subject experienced the event on the same days as of vaccination. Concurrent reported oesophagitis and vomiting suggest an infection of upper digestive tract. The case lacks data for medical assessment.

6.4.2.4.2. Intussusception

During the period of this report, four cases of intussusception have been received.

In case **B0663295A** intussusception was reported together with anaphylactic reaction, this case is summarised in section [6.4.2.5.1](#) on anaphylactic reaction.

The other cases are summarised below.

Case **B0643201A**- MedDRA Preferred Terms: Intussusception, Haematochezia, Peritoneal disorder, Gastrointestinal inflammation, Gastrointestinal hypomotility, Intestinal dilatation, Abdominal rigidity, Body temperature decreased, Hypotonic-hyporesponsive episode, Rash maculo-papular, Sepsis

This case was reported by the Poland regulatory authority and described the occurrence of suspected intussusception in a 9-week-old subject of unspecified gender who was vaccinated on 6 January 2010 with unspecified doses of Rotarix™, Infanrix hexa™ and Prevnar. On 11 January 2010, 5 days after vaccination, the subject experienced merging maculo-papular rash and hypotonic-hyporesponsive episode. Subsequently, the child was hospitalised. On admission, the child had decreased body temperature (35.9 deg. C).

An ultrasonography showed dilated intestinal loops, intestinal hypomotility and traces of fluid in the peritoneum. The child was referred to the Infectious Disease Clinic because of suspected sepsis. During the first days of admission, the child was in a serious condition and experienced haematochezia, hard abdomen and intestinal hypomotility. No pathological flora was isolated from the blood culture. Because of the vaccination with Rotarix, the possibility of spontaneously resolved intussusception was considered. At the time of reporting the events were improved.

Company comment: The events occurred 5 days after multiple vaccinations in a 9-week-old subject. Spontaneously resolved intussusception was considered.

Case **B0651961A**- MedDRA Preferred Terms: Intussusception, Rectal haemorrhage, Diarrhoea haemorrhagic, Lymphadenopathy, Pyrexia, Vomiting, Dyspepsia, Scar, Wound infection, Diarrhoea

This case was reported by a physician and described the occurrence of intussusception in a 6-month-old male who was vaccinated with Rotarix™, Infanrix hexa™ and Prevenar. The subject had no medical history. Previous and/or concurrent vaccination included Infanrix hexa™ and Prevenar given on 12 January 2010. On 5 February 2010, the subject received the 1st dose of Rotarix™. On 12 March 2010, the subject received unspecified doses of Infanrix hexa™ and Prevenar and the 2nd dose of Rotarix. On 1 May 2010, the subject experienced fever, vomiting, digestive discomfort (painful crises) proctorrhagia, blood diarrhea, ileo-caecal intussusception of 12 cm and lymphadenopathy (presence of lymph nodes confirmed via echography).CRP was 2.21. The subject was hospitalised and treated with injection of contrast product (enema administration) to reduce the invagination but it was only partially successful. Then, he was operated without any resection of the intestine. According to the paediatrician, this was a mechanical invagination due to the presence of lymph nodes. On 3 May 2010, the subject experienced fever. On 4 May 2010, the subject experienced diarrhoea. A stool analysis was performed and showed the presence of adenovirus (type40/41). Following the surgery, the subject developed wound infection. At the time of reporting, the events were resolved with sequelae (scar).

Company comment: This 10-month-old subject experienced intussusception 7 months after multiple vaccinations, in the context of gastroenteritis.

Case **B0656738A** - MedDRA Preferred Terms: Intussusception, Small intestinal resection, Vomiting, Colectomy, Abdominal pain

This case was reported by a nurse and described the occurrence of intussusception in a 10-month-old female who was vaccinated with Rotarix, Infanrix hexa™ and Prevenar. Previous and/or concurrent vaccination included unspecified dose Infanrix hexa™, Rotarix™ and Prevenar given on 20 August 2009 and on 21 September 2009. On 22 October 2009, the subject received unspecified doses of Infanrix hexa™ and Prevenar. On 12 May 2010, 7 months after vaccination with Infanrix hexa™ and Prevenar, 8 months after vaccination with Rotarix, the subject experienced vomiting with severe abdominal pain. She was admitted for gastroenteritis. On 13 May 2010, intussusception was diagnosed with barium enema; right hemicolectomy and a small bowel resection were done the same day. The subject was hospitalised 2 days in ICU and then ward. At the time of reporting, the events were resolved.

Company comment: This 10-month-old subject experienced intussusception 7 months after multiple vaccinations, which make unlikely the causality of Infanrix hexa™.

6.4.2.4.3. General disorders and administration site conditions

6.4.2.4.4. Abscess sterile, Injection site abscess sterile and vaccination site abscess sterile

Five cases of abscess sterile (of which three cases in the same subject) as well as two cases coded with the MedDRA Preferred Terms injection site abscess sterile or vaccination site abscess sterile have been received during this reporting period. These cases are summarised below.

Cases **D0063315A**, **D0063315B** and **D0063315C** - MedDRA Preferred Term: Abscess sterile

These cases were reported by a physician and described the occurrence of sterile abscess in a male subject at 4, 6 and 16-months of age within some months after vaccination with the 2nd, 3rd and 4th dose of Infanrix hexa™. The subject had no disturbance of immune system. The first vaccination with Infanrix hexa™ as well as all other vaccinations were well tolerated. The first abscess discharged spontaneously with pus and resolved with sequelae (scar). The second and third times abscesses were opened by puncture to reduced scarring and discharged with pus.

Company comment: Case of recurrent sterile abscess at injection sites after vaccination with Infanrix hexa™.

Case **D0068815A** - MedDRA Preferred Terms: Abscess sterile, Injection site swelling, Injection site induration, Scar, Malaise

This case was reported by a physician and described the occurrence of sterile abscess in a 17-month-old male who was vaccinated with Infanrix hexa™. The subject's medical history included status post nephropyloroplasty. After the 1st dose of Infanrix hexa™ the subject was ill. On 11 January 2010 the subject received the 2nd dose of Infanrix hexa™ (left thigh). Within one year after vaccination, the subject experienced induration at injection site with afterwards abscess formation. Abscess was punctuated ambulatory and smear was analysed. Bacteria could not be detected. In the following a scar developed. At the time of reporting, the subject was in good health.

Company comment: This 17-month-old subject experienced injection site abscess sterile within one year after vaccination with Infanrix hexa™. No injection sites abscesses were reported at other vaccinations. The drainage of this abscess revealed sterile secretion.

Case **D0068941A** - MedDRA Preferred Terms: Abscess sterile, Injection site reaction, Injection site nodule, Injection site swelling

This case was reported by a physician and described the occurrence of possible sterile abscess in a 2-year-old male who was vaccinated with Infanrix hexa™. The subject's medical history included severe injection site reaction(s) post-vaccination with the primary course of vaccination with Infanrix hexa™. The first three doses of Infanrix hexa™, were given on 13 February 2009, 20 March 2009 and 13 May 2009. On 30 July 2010 the subject received a booster with the fourth dose of Infanrix hexa™ (left thigh). Approximately four weeks post-vaccination, end of August 2010, the subject experienced very severe injection site reaction and possible sterile abscess at injection site. Sonography of the left thigh in the area of injection site, showed two structures which were overlapping or directly bordering on each other. The upper of these structures appears longitudinal oval, embedded about one cm deep, was distinctly hypoechogenic, surrounded by a thin hyperechogenic wall and has a size of 3.3 x 0.7 x 1.5 cm. After distal crossing the second of these structures was oval with mixed hypoechogenic content and with a size of 2.6 x 1.2 cm. No inner perfusion could be detected. The lower structure was consistent with possible injection site granuloma. For the upper structure injection site abscess could not be excluded completely, but sterile abscess was considered to be rather unlikely due to lack of accompanying fever, redness and pain. At the time of reporting, on 21 September 2010, the events were still ongoing.

Company comment: The subject experienced injection site reaction one month after vaccination with a booster dose of Infanrix hexa. Except injection site swelling, inflammatory signs were absent. Sonography revealed two structures that have been interpreted as possible granuloma and possible abscess.

Case **D0067836A** - MedDRA Preferred Terms: Injection site abscess sterile, Injection site swelling

This case was reported by the German regulatory authority and described the occurrence of injection site abscess sterile in an 18-month-old female who was vaccinated with Infanrix hexa™. The subject was healthy and has no underlying or concurrent medical conditions or other risk factors. Previous and/or concurrent vaccinations with Priorix™ Tetra, Prevenar, and NeisVac-C given on unspecified dates, have been well tolerated. After previous vaccinations with Infanrix hexa™, given on an unknown date intramuscularly in the right thigh, the subject experienced late sterile abscess which was drained by incision. On 06 January 2010 the subject received a booster with the fourth dose of Infanrix hexa™ (left thigh). Approximately 34 days post-vaccination the subject experienced injection site swelling of about 5 cm at the left thigh anterolaterally that was diagnosed to be a sterile abscess at injection site. At first the subject was treated conservatively including local cooling and hydroxycitric acid topically. The events improved. On 17 March 2010 the abscess was opened by puncture with a drain tube. Discharge from sterile abscess showed a small amount of yellowish pus. The events resolved.

Company comment: The subject had a sterile abscess after an unspecified dose of Infanrix hexa™. The subject developed an injection site sterile abscess 34 days after a booster dose of Infanrix hexa™. The abscess required drainage which revealed a small amount of pus that was not analyzed. No treatment was reported.

Case **D0069205A** - MedDRA Preferred Terms: Vaccination site abscess sterile

This case was reported by the German regulatory authority and described the occurrence of vaccination site abscess sterile in a 10-month-old male who was vaccinated with Infanrix hexa™. The subject's past medical history was not provided. Previous vaccination with the first two doses of Infanrix hexa™ given on 01 July 2010 and 23 July 2010, have been well tolerated. On 08 September 2010 the subject received the third dose of Infanrix hexa (left thigh). Approximately 23 days post-vaccination, on 01 October 2010, the subject experienced vaccination site abscess sterile. Diagnosis was confirmed by spontaneous perforation and discharge of pus. The subject was treated ambulatory, but was not hospitalised for the event. At the time of reporting, on 11 October 2010, the event was unresolved.

Company comment: Previous first two doses of Infanrix hexa™ at unknown sites were well tolerated. The abscess drained spontaneously with pus discharge. The analysis of the pus was not reported.

6.4.2.4.5. Injection site necrosis

One case of injection site necrosis was received during the period of this report.

Case **D0069186A** - MedDRA Preferred Terms: Injection site necrosis, Injection site vesicles, Injection site erythema

This case was reported by a physician and described the occurrence of injection site necrosis in 11-week-old male who was vaccinated on 08 October 2010 with the first dose of Infanrix hexa™ (left thigh). The subject has no underlying or concurrent medical conditions or other risk factors. On 10 October 2010, the subject experienced an injection site blister about 2 Euro coin-sized with surrounding redness (injection site redness). The blister looked like a burn blister. When the blister was removed a central site of skin necrosis was found (injection site necrosis). The site was treated regularly like a burn blister. At the time of reporting the events was unresolved.

Company comment: The subject experienced injection site necrosis 2 days after administration of the first dose of Infanrix hexa™. There was a blister at the injection site which was removed and injection site necrosis observed. It is unclear whether necrosis was primary event or occurred as a result of blister removal.

6.4.2.4.6. Injection site nodule and Nodule

Twenty-six case reports of injection site nodule and 3 cases of nodule have been received during the period of this report.

Three cases met the criteria for „regulatory“ seriousness. All 29 cases were spontaneously reported. The majority of cases lack data for adequate assessment e.g. specific site of injection when concurrent vaccines are given, and/or time to onset and/or time to outcome.

These cases are summarised in tabular format below (Tables 7 and 8). Cases with bolded event terms are also analysed/summarised in the relevant sub-sections of section 6.4 of this PSUR.

6.4.2.5. Immune system disorders

6.4.2.5.1. Anaphylactic reaction and anaphylactic shock

During the period of this report, four cases of anaphylactic reaction or anaphylactic shock have been reported.

Case **B0652232A** - MedDRA Preferred Term: Anaphylactic shock

This case was reported by the Spanish regulatory authority and described the occurrence of anaphylactic shock in a 2-year-old female who was vaccinated with the 1st dose of Infanrix hexa™ and unspecified dose of Menjugate (non-GSK). On 16 February 2009, less than one day after vaccination, the subject experienced anaphylactic shock. The subject was hospitalised. At the time of reporting, the event was resolved.

Company comment: This 2-year-old female subject experienced anaphylactic shock less than one day after multiple vaccinations. This report lacks important information such as anaphylaxis's symptoms and treatment.

Case **B0663295A** - MedDRA Preferred Terms: Anaphylactic reaction, Haematochezia, Intestinal obstruction, Intussusception, Somnolence, Pallor, Vomiting, Pulse abnormal, Capillary disorder

This case was reported by a physician and described the occurrence of anaphylaxis in a 6-month-old male who was vaccinated with unspecified dose of Infanrix hexa™ and unspecified dose of Rotarix. On 26 June 2010, 20 minutes after vaccination, the subject was mildly drowsy and pale. He was brought back home where he had 10 times clear yellowish vomiting. He had no diarrhea. Six hours after vaccination, the subject was markedly pale and drowsy. He was hospitalised. At admission, the subject was drowsy, pale, had a weak peripheral pulse and delayed capillary refill. The temperature was 37.6 degC, blood pressure 120/80 mmHg and pulse rate 130 beats/min. The subject was treated with intravenous fluid(s). Anaphylaxis was diagnosed, leading to treatment with adrenaline and antihistamine. The laboratory tests performed showed hematocrit 36%, white blood cell count 10700/mm3, neutrophils 60%, platelet count 300000/mm3 and normal electrolyte. On 27 June 2010, the subject experienced bilious vomiting and jelly stool. The abdomen x-ray showed abdominal obstruction and abdomen ultrasound revealed intussusception.

The intussusception was closely reduced by medical air. The subject was treated with ceftriaxone sodium (Rocephin). On 28 June 2010, the subject was in a better condition and was discharged from hospital with oral antibiotics as treatment. At the time of reporting the events were resolved. The physician concluded this case as anaphylaxis due to Infanrix hexa™. He considered that the onset of the intussusception was too close to be related to vaccination.

Company comment: This 6-month-old male subject experienced the event 6 hours after multiple vaccinations. The reported symptoms of anaphylaxis are likely to be associated with the intussusception episode that was diagnosed within 24 hours after vaccination.

Case **B0664784A** - MedDRA Preferred Terms: Anaphylactic reaction, Agitation, Heart rate increased, Conjunctival hyperaemia, Urticaria, Crying

This case was reported by the Italian regulatory authority via a physician and described the occurrence of anaphylactic reaction in a 4-month-old male who was vaccinated with the 2nd dose of Infanrix hexa™ and Prevenar. On 2 July 2010, 1 hour after vaccination, the subject experienced anaphylactic reaction with widespread urticaria, agitation, accelerated heart rate, conjunctival redness and weeping. The subject was hospitalised and treated with chlorpheniramine (Clorfenamina) and cortisone. On 2 July 2010, the events were resolved.

Company comment: Symptoms occurred 1 hour after multiple vaccinations. The reported symptoms provide insufficient evidence to confirm the diagnosis of anaphylaxis.

Case **D0068761A** - MedDRA Preferred Terms: Anaphylactic reaction, Hypersensitivity, Dyspnoea, Urticaria, Angioedema, Bronchospasm, Stridor

This case was reported by a physician and also by the German regulatory authority and described the occurrence of anaphylaxis in a 30-month-old female who was vaccinated with a 4th dose of Infanrix hexa™. The first three doses of Infanrix hexa™ for basic immunisation on 15 May 2008, 16 July 2008 and 29 August 2008 were well tolerated. The subject's medical history included myocarditis in summer 2009 with cerebral edema, post-ischemic encephalopathy, cerebral convulsion and minimal response state. The subject was severely disabled after cerebral infarction and haemorrhage during cardiac assist therapy. The subject had no history of allergies to drugs. Concurrent medications included Spironolactone (Aldactone), Hydrochlorothiazide, acetylsalicylic acid (ASS), Topiramate (Topamax), Clobazam (Frisium), sodium valproate + valproic acid (Ergenyl chrono), Lamotrigine (Lamictal), macrogol + sodium chloride + sodium hydrogen carbonate + potassium chloride (Movicol junior), Baclofen, Melatonin, Sodium chloride (NaCl) and Omeprazole (Antra MUPS). On 24 August 2010, approximately 45 to 60 minutes after vaccination, the subject had a swollen face and was wheezing. The subject experienced anaphylaxis with severe dyspnea, generalized urticaria, quincke's edema and bronchoconstriction. None of the following symptoms or signs were present: hypotension, dizziness, syncope, nausea, vomiting, diarrhea, Coombs' positive haemolytic anemia, signs for bone marrow suppression, fever, arthropathy, lymphadenopathy, proteinuria, eosinophilia, skin rash or contact dermatitis. The subject received prednisone (Rectodelt) and an emergency physician was called.

The emergency physician set up an intravenous line and administered volume, dimethindene maleate (Fenistil) and ranitidine hydrochloride (Ranitidin). Additionally the infant inhaled adrenaline (Adrenalin). After successful stabilisation, the subject was admitted to a pediatric intensive care unit. The treating paediatrician diagnosed dyspnea, inspiratory stridor, edema and urticaria over the body. The subject was diagnosed with allergic reaction grade III. In hospital the subject again received adrenaline and volume and additional prednisolone sodium succinate (Solu-Decortin) and oxygen via a mask. After several hours the events were resolved. On 25 August 2010 the subject was discharged from hospital without any symptoms. The physician considered the events were probably related to vaccination with Infanrix hexa™.

Company comment: This 30-month-old female subject experienced anaphylactic reaction after vaccination with the 4th dose of Infanrix hexa™. The reported symptoms are compatible with anaphylaxis as there is sufficient evidence to meet the case definition of anaphylaxis by the Brighton Collaboration criteria. Of note, several concurrent medications with unknown start date.

6.4.2.6. Infections and infestations

6.4.2.6.1. Abscess, Abscess limb, Incision site abscess, Injection site abscess, Vaccination site abscess

During the reporting period, 17 cases were received including one of the following MedDRA Preferred Terms: abscess (n=4), abscess limb (n=1), incision site abscess (n=5), injection site abscess (n=10) and/or vaccination site abscess (n=2).

These cases are summarised in the below tables. Cases with bolded event terms are also analysed/summarised in the relevant sub-sections of section 6.4 of this PSUR.

6.4.2.6.2. Cellulitis and injection site cellulitis

During the period under review, 7 serious cases have been received with the event cellulitis and 1 serious case was received with the event injection site cellulitis. These cases are summarised below.

Case **B0661012A** – MedDRA Preferred Terms: Cellulitis, Injection site erythema, Pyrexia, Injection site swelling

This case was reported by a physician and described the occurrence of phlegmon in a 2-year-old female who was vaccinated with the 4th dose of *Infanrix hexa*TM. On 11 June 2010, 2 days after vaccination with *Infanrix hexa*TM, the subject experienced redness and swelling at injection site and fever. CRP level was 32.8 mg/l. The subject was hospitalised and treated with antibiotics (Broad-spectrum antibiotic). At the time of reporting, all events were resolved.

Case **B0661014A** – MedDRA Preferred Terms: Cellulitis, Oedema peripheral, Erythema

This case was reported by a physician and by a regulatory authority and described the occurrence of phlegmon in a 23-month-old female after vaccination with the 4th dose of *Infanrix hexa*TM and the 2nd dose of *Havrix*TM 720. One day after vaccinations, the subject experienced erythema and swelling of the whole left upper arm. It was not known which vaccine was administered on which side. The subject was hospitalised and treated with antibiotics (Broad-spectrum antibiotic). CRP level was 21.1 mg/l. At the time of reporting, all the events were resolved.

Case **B0661015A** – MedDRA Preferred Terms: Cellulitis, Erythema, Swelling

This case was reported by a physician and described the occurrence of phlegmon, erythema and swelling in the area of injection site (expansion until sternum) in a 2-year-old female less than 1 day after vaccination with an unspecified dose of Infanrix hexa™. The subject was hospitalised and treated with antibiotics (Broad-spectrum antibiotic). Laboratory results: WBC: 12.6, CRP: less than 8 mg/L. At the time of reporting, all the events were resolved.

Case **B0677146A** – MedDRA Preferred Term: Cellulitis

This case was reported by a physician and described the occurrence of cellulitis in an 18-month-old female 2 days after vaccination on 14 September 2010 with a 4th dose of Infanrix hexa™. The subject was hospitalised and discharged on 20 September 2010.

Case **D0067880A** – MedDRA Preferred Term: Cellulitis

This case was reported by the German regulatory authority and described the occurrence of phlegmon on the left thigh in a 22-month-old male 2 days after vaccination with the 4th dose of Infanrix hexa™ (left thigh). Previous vaccinations with the first three doses of Infanrix hexa™ were well tolerated. The subject was hospitalised for an unknown period of time. The event was confirmed by serology. After about six days the event was resolved.

Case **D0069118A** – MedDRA Preferred Terms: Cellulitis, Injection site erythema, Injection site swelling, Injection site warmth, Injection site induration

This case was reported by a regulatory authority and described the occurrence of phlegmon in a 3-year-old female who was vaccinated with Infanrix hexa™. Subject's father suffered from breathing complaints and psoriasis. The subject was the 3rd child of the family. Pregnancy was under strain of nicotine abuse. Birth and development were normal. Previous vaccinations with Infanrix hexa™ given on 3 August 2008 and 24 February 2009 were well tolerated. On 28 September 2010 the subject received the 3rd dose of Infanrix hexa™ (right upper arm). On 30 September 2010, the subject experienced phlegmon on right upper arm with significant redness, swelling, warmth and induration at injection site. The subject was hospitalised from 30 September 2010 till 5 October 2010 and treated by antibiotics with intravenous cefuroxime sodium (Cefuroxim) then switched to oral cefuroxime sodium. The upper arm was treated by coolin with hydroxychinolin. Blood sample showed mild monocytosis (0.07) and eosinophilia (0.06). White blood cell increased to 15.83gpt/l. Redness, swelling and induration improved. The subject was discharged from hospital on 5 October 2010 in stable general condition still with mild induration at injection site on right upper arm.

Case **D0069190A** – MedDRA Preferred Terms: Cellulitis, Erythema, Oedema peripheral, Blister, Purulence, Skin warm, Ulcer, General physical health deterioration, Induration, Injection site erythema, Tympanic membrane hyperaemia, Vaccination complication

This case was reported by a physician via a regulatory authority and described the occurrence of phlegmon of arm in a 26-month-old female who was vaccinated with Infanrix hexa™. Previous vaccinations included Infanrix hexa™ given on 08 February 2010, 12 March 2010 and 24 April 2010, which were well tolerated. On 23 September 2010 the subject received the 4th dose of Infanrix hexa™ (right upper arm). Less than one day after vaccination, the subject experienced Ulcus cruris, purulent secretion, vaccination site warmth, vaccination site redness and vaccination site swelling, phlegmon of right upper arm. She did not develop fever. Bacterial superinfection was suspected. Due to staphylogenic phlegmon of right upper arm, the subject was hospitalised on 25 September 2010 for 3 days. On admission examination, the subject's general condition was mildly reduced. Skin at right upper arm was warm, red and indurated. There were single partly opened blister which partly were weeping. Injection site showed redness without secretion. Eardrums at both sides showed redness. All other clinical physical examinations were normal. Body temperature 37.8degC, CRP 1.6mg/dl, Leukocyte 9.9 (Granulocyte 56%, Lymphocytes 35%). Possible superinfection and vaccination reaction at right upper arm were diagnosed. Wound smear was negative for Staphylococcus aureus and haemolytic Streptococcus. By differential diagnosis, bacterial superinfection has been excluded. The subject was treated with cefuroxime sodium (Cefuroxim) and octenisept bandages. Symptoms improved. On 27 September 2010, the subject was discharged from hospital in good general condition. There was one small area at skin, which was still mildly weeping.

Case **B0675146A** – MedDRA Preferred Terms: Injection site cellulitis, Injection site oedema, Blister, Injection site erythema, Injection site pain, Injection site induration, Injection site vesicles, Lymphadenopathy, Ecchymosis, C-reactive protein increased, Leukocytosis, Skin chapped

This case was reported by the French regulatory authority and described the occurrence of injection site cellulitis in a 17-month-old male who was vaccinated with Infanrix hexa™, and Meningitec (non-GSK). The subject had no known relevant medical history. First administration of Infanrix hexa™ in October 2009 was without reported adverse events. On 01 July 2010, the subject received booster doses of Infanrix hexa™ and Meningitec (unknown injection sites). On the same day in the evening, the subject presented with edema and phlyctena at injection site on right thigh. Size of edema increased thus the subject was taken to the emergency unit on 03 July 2010. On admission, he presented on right thigh with an erythema plaque of 15 cm long, painful, indurated and bullous at injection site associated with inguinal adenopathy (more than 1 cm of diameter). Left thigh was without local reaction and without palpable adenopathy. During the following hours, edema increased and extended over three quarter of right thigh with two or three phlyctenules. Ecchymotic aspect was noticed on peri-phlyctenules (coded ecchymosis at site). Post vaccinal cellulitis was diagnosed. The subject had neither fever nor abdominal pain. Lab tests revealed increased C-reactive protein at 25 mg/l and hyperleukocytosis at 11.4 G/L. Bacteriological tests performed on punctured phlyctenules showed no pathogenic microorganisms.

The subject received one dose of intravenous ceftriaxone sodium (Rocephine), then *saccharomyces boulardii* (Ultralevure) and amoxicillin trihydrate + potassium clavulanate (Augmentin) prescribed for 10 days.

On 08 July 2010, the subject returned to emergency unit. He had severe fever for 24 hours. On admission he presented with anal bleeding, diarrhea, candidiasis on buttocks and nasopharyngitis with both congested eardrums (all incidental events). At vaccine injection site on right thigh, skin was mildly indurated, without petechia or inflammation. Lab test showed decreased C-reactive protein level to 7 mg/L and normalisation of white blood cell count at 7 G/L. Blood culture was positive for coagulase negative staphylococcus (unspecified level). Augmentin was discontinued and the subject was treated with Rocephine firstly intravenously and then intramuscularly during 48 hours. On 21 July 2010, skin at edema area was a little crackled but with a normal colour. A mild induration persisted at injection site. The subject was well. On an unspecified date, injection site cellulitis resolved.

Company comment: In all described cases, the subjects were aged between 17 months and 3 years and received their booster dose of Infanrix hexa™. Six of them received antibiotics. In six cases, no causing agent of cellulitis was identified. In case D0067880A, cellulitis was confirmed by unspecified serology. In case B0675146A, a co-suspect vaccine was involved with unknown injection sites for both vaccines. Bacteriological tests were negative at the reaction site. Blood culture was positive for coagulase negative staphylococcus 8 days after vaccines administration.

6.4.2.6.3. Meningitis, Meningitis aseptic and meningitis pneumococcal

During the period under review, 3 cases were received with the MedDRA Preferred Terms meningitis (n=1), meningitis aseptic (n=1) or meningitis pneumococcal (n=1).

In case **D0068409A**, meningitis was reported together with Kawasaki's disease. This case is described in section 6.4.2.10.1 on Kawasaki's disease. Meningitis was likely suspected but no details were reported. The final diagnosis was Kawasaki's disease. The other cases are described below.

Case **B0651993A**- MedDRA Preferred Term: Meningitis aseptic

This case was reported by the Spanish regulatory authority and described the occurrence of aseptic meningitis in an 18-month-old male 1 day after vaccination on 02 December 2008 with an unspecified dose of Infanrix hexa™. On 18 December 2008, the event was resolved.

Company comment: An 18-month-old subject developed aseptic meningitis 1 day after vaccination with unspecified dose of Infanrix hexa™. No data confirming this event were reported.

Case **D0066195A**- MedDRA Preferred Terms: Meningitis pneumococcal, Pyrexia, Restlessness, Muscle spasms, Respiratory disorder, Salivary hypersecretion, Daydreaming, Hypertension, Hemiplegia, Cerebral haemorrhage, Motor dysfunction

This case was reported by a consumer, the subject's grandmother, via the GSK-sponsored internet site and described the occurrence of pneumococcal meningitis in a 4-month-old male who was vaccinated with Infanrix hexa™ and Synflorix™. The subject had received complete immunisation with two doses of Synflorix™. A physician or other health care professional has not verified this report. The subject was breast-feeding. On an unspecified date the subject received unspecified dose of Infanrix hexa™. In January 2010, at an unspecified time after vaccination with Infanrix hexa™, the subject experienced fever up to 39.5 degC and was treated with paracetamol. The subject was drinking normally. In the evening, at 21:30 the subject developed restlessness and cramps and was hospitalised.

Computerised tomogram was without findings. Meningitis was suspected and the subject treated accordingly. Because of respiration problems the subject received oxygen. In the morning at 05:00 respiration had stabilised. After lumbar puncture the subject was diagnosed with pneumococcal meningitis. The genotype was identified as C15. The subject was treated with phenobarbitone (Luminal) and antibiotics. Three days later the subject was in bad condition, with salivation, absent mind, high blood pressure and right sided paralysis. The subject was treated with heparin. On 18 January 2010 a magnetic resonance tomogram was performed and showed severe cerebral hemorrhage in the front of both halves of the brain. The subject had right-sided motor dysfunction. The subject was transferred to a neurosurgical unit. Treatment included blood transfusions and other antibiotics, because inflammatory parameters had increased. At the time of reporting the outcome of the events was unspecified.

Company comment: A 4-month-old male subject experienced pneumococcal meningitis on unspecified time after vaccination with Infanrix hexa™ and Synflorix™. Based on CSF results, the subject was diagnosed with pneumococcal meningitis.

6.4.2.6.4. Sepsis

During the period of this report 4 cases of sepsis have been identified.

In case **B0643201A** suspected sepsis was reported in association with suspected intussusception. This case is described in more details in section 6.5.2.4.2 on intussusception. No data were available to confirm the diagnoses.

In case **D0064259A** the subject died. This case is described in more details in section 6.4.1 on cases with a fatal outcome. According to the autopsy report the cause of death was SIDS and viral infection. No data were available to confirm the diagnosis of sepsis.

In case **D0068409A** sepsis was reported together with Kawasaki's disease. This case is described in section 6.4.2.10.1 on Kawasaki's disease. Bacterial gastroenteritis and sepsis were suspected but not confirmed.

Case **D0065893A** – MedDRA Preferred Terms: Ileus paralytic, Peritonitis, Ileostomy, Microcephaly, Inguinal hernia, Acute abdomen, General physical health deterioration, Ascites, Sepsis, Vomiting, Leukocytosis, Hyponatraemia, Muscle disorder

This case was reported by the Dutch regulatory authority and described the occurrence of paralytic ileus in a 3-month-old male who was vaccinated with Infanrix hexa™ and Prevenar. The subject was born prematurely at 28+1 weeks of gestation by caesarean section, because of maternal epilepsy and somnolence and suspicion of amniotic infection syndrome. After birth the subject had valproate embryopathy, dyspnoea syndrome, arterial hypotension, persistent ductus arteriosus which was closed by medication, persistent foramen ovale, apnea-bradycardia syndrome, conjunctivitis, possible infection and urinary transportation disorder grade 1. First dose of Infanrix hexa™ and Prevenar had been well tolerated. After second vaccination, on 20 May 2009, the subject was hospitalised with symptoms of gastroenteritis. Next day his general condition worsened, because of acute abdomen syndrome. Sonogram showed ileus with dilated intestinal loops. Laparotomy on 21 May 2009 showed no mechanic correlate of the symptoms, nor any pathology of the intestine. The subject had foul-smelling ascites and septic picture. Ileostomy was performed. Because of septic picture, antibiotic treatment with Ampicillin, tobramycin and metronidazole was started. No infective germs were found in stool and blood. On 25 May 2009 a gradual return to normal food was started. This was well tolerated at first, but on 28 May 2009 the subject again developed recurrent vomiting and leukocytosis which improved. Ampicillin trihydrate was stopped on 04 June 2009, tobramycin on 30 May 2009 and metronidazole on 02 June 2009. On 03 June 2009 the subject's condition again worsened, with dilated abdomen and vomiting. Inflammatory parameters increased and sonogram showed subileus. This improved after treatment with tobramycin, metronidazole and Unacid and after three days return to normal food was again started. Antibiotic treatment was stopped on 05 June 2009. Persisting hyponatremia was treated by oral NaCl. As no microbiological cause of subileus was found, biopsy was performed on 05 June 2009 which showed no sign for Hirschsprung disease. Inguinal hernia, found by sonogram on 05 June 2009, was removed. In sonogram, the side ventricles of brain were abnormal. The subject showed fluctuating muscle tone and was transferred to a neuropaediatric unit on 22 June 2009. The subject was in good general condition on 03 July 2009.

Company comment: No etiological agent causing acute abdomen and ascitis were reported. Sepsis was suspected but not confirmed.

6.4.2.7. Musculoskeletal and connective tissue disorders

6.4.2.7.1. Nodule on extremity

During the reporting period, two cases were reported with the MedDRA Preferred Term nodule on extremity.

Case **B0637004A** – MedDRA Preferred Terms: Nodule on extremity, Crying

This non-serious case was reported by the Italian regulatory authority and described the occurrence of thigh nodule in a 6-month-old male who was vaccinated with Infanrix hexa™ on 27 November 2009 (injection site unknown). On 12 February 2010, 77 days after vaccination with Infanrix hexa™, the subject experienced thigh nodule and persistent crying. The subject was treated with antibiotics. At the time of reporting, the events were resolved.

Company comment: This case lacks information on injection site of Infanrix hexa™.

In case **D0067703A** the event was reported together with abscess limb. This case was described in section 6.4.2.6.1 on abscess limb.

6.4.2.8. Nervous system disorders

6.4.2.8.1. Cerebral atrophy

During the period of this report, one case of cerebral atrophy was received.

Case **D0067158A** - MedDRA Preferred Terms: Convulsion, Partial seizures, Cerebral atrophy, Demyelination, Petechiae, Developmental delay, Schamberg's disease, Rhinitis

This serious case was reported by the Germany Regulatory Authority and described the occurrence of seizure in an infant male who was vaccinated with 3 doses of Infanrix hexa™, 3 doses of Prevenar, 3 doses of RotaTaq, 2 doses of Priorix™ Tetra and 1 dose of Menjugate. The subject's medical history included mother's insemination, cesarean section delivery at 36 + 3 weeks of pregnancy, HELLP syndrome during mother's pregnancy, postpartum hemorrhagic gastritis, hyperbilirubinemia, postpartum anemia, treated with transfusion. According to the report about a suspicion of vaccine damage, signed on 29 December 2009 by paediatrician, in August 2008, the subject developed for the first time petechiae. Haematological examinations of petechiae cause were missing. The subject was hospitalised due to first cerebral seizure, petechiae and serous rhinitis at the age of 7-months, in October 2008. Benign infant partial epilepsy Watanabe was suspected. Plasmatic coagulation disorder was excluded. Beginning of 2009, a statomotoric developmental delay was suspected and confirmed in March 2009 during infant medical check-up, at the age of 11 months. Purpura pigmentosa progressive was diagnosed at that time. NMR tomography, performed at the age of 15 months, in July 2009, showed mild increasing cerebral atrophy with wide inner and outer subarachnoid spaces. State of myelinization was considered to be like 11 months. Examinations of human genetics and molecular genetics in December 2009 were normal. The outcome of the events was unspecified.

Company comment: This case describes a subject who was diagnosed with cerebral atrophy and suspected Watanabe epilepsy after multiple vaccinations. The subject received complete vaccinations according to his age. The reported subject's conditions (postpartum hemorrhagic gastritis, hyperbilirubinemia, postpartum anemia, treated with transfusion and suspected epilepsy) might have contributed to an observed psychomotor retardation.

6.4.2.8.2. Cerebral haemorrhage

During the period of this PSUR, two cases of cerebral haemorrhage were received. They are described below.

Case **B0666511A** - MedDRA Preferred Terms: Cerebral haemorrhage, Hemiparesis, Lethargy, Convulsion, Crying, Nervousness, Tension.

This serious case was reported by a physician and described the occurrence of brain hemorrhage in a 4-month-old female who was vaccinated with the 2nd doses of Infanrix hexa™ and Prevenar. Less than one month after first vaccinations, the subject cried a lot, she was jumpy and easily startled. One day after vaccination with the 2nd doses, the subject experienced lethargy, right-sided hemiparesis and brain hemorrhage. The subject was hospitalised. NMR of brain showed left side cerebral hemorrhage involving capsula interna and basal nuclei. The subject was treated with hydration therapy, intravenous fluids and corticosteroid. According to the follow-up information, motion awkwardness and paresis of right hand have decreased and the leg had a full motion. Seizure did not recur. At the time of reporting, the events were resolved with sequelae.

Company comment: A 4-month-old subject experienced cerebral haemorrhage 1 day after multiple vaccinations. Provided information is limited only to NMR findings and did not provide results of other tests. Such short time to onset makes vaccinations as uncertain cause of this event. Information on investigation of other causes of haemorrhage like infection diseases, coagulation disorders were not provided.

The second case **D0066195A** was reported by a consumer and described a 4-month-old subject who experienced cerebral haemorrhage in the context of pneumococcal meningitis. This case is described in more details in section [6.4.2.6.3](#) on meningitis.

6.4.2.8.3. Seizures

Atonic seizures, Clonic convulsion, Clonus, Convulsion, Convulsions local, Febrile convulsion, Grand mal convulsion, Myoclonus, Partial seizures, Tonic convulsion

During the reporting period, 117 individual case reports were received including one of the following MedDRA Preferred Terms: atonic seizures (n=1), clonic convulsion (n=1), clonus (n=1), convulsion (n=55), convulsions local (n=1), febrile convulsion (n=54), grand mal convulsion (n=18), myoclonus (n=4), partial seizures (n=3) and/or tonic convulsion (n=3). In some instances more than one MedDRA Preferred Terms was included to describe the same event.

Note compared to the previous PSURs epilepsy, infantile spasms, petit mal epilepsy and status epilepticus are described separately from the other types of seizures.

These cases are summarised in the below tables.

Table 11 Summary information for complete data set, n=117

Patient age (n=114)	Range	months	1-36
	Median	months	5
Patient gender (n=112)	Male	n	54
	Female	n	58
Report type	Spontaneous	n	117
Type of convulsion*	Febrile	n	82
	Afebrile	n	35
Time to onset of event (n=108)	Range		less than 1 day to 3 weeks
	Median	days	same day
Outcome	Resolved	n	81
	Resolved with sequelae	n	3
	Improved	n	5
	Fatal	n	1
	Unresolved	n	5
	Unknown	n	22
Cases where concomitant vaccine was administered		n	92

*note that some febrile seizures were described with the MedDRA Preferred Terms 'Convulsion' and 'Pyrexia' rather than the Preferred Term 'Febrile convulsion'.

Subject age was provided in 114 reports included in the analysis and ranged from 1 month to 3 years with a median of 5 months. Subject gender was provided in 112 reports and included 54 males and 58 females. TTO was provided in 108 reports and ranged from less than 1 day to 3 weeks (median: less than 1 day).

Epilepsy, Petit mal epilepsy, Infantile spasms, Status epilepticus

During this reporting period 11 cases of epilepsy, 4 cases of petit mal epilepsy, 2 cases of infantile spasm and 4 cases of status epilepticus were reported.

CONFIDENTIAL

CONFIDENTIAL

These cases are summarised in the below tables. Cases with bolded event terms are also analysed/summarised in the relevant sub-sections of section 6.4 of this PSUR.

Table 12 Summary information for complete data set, n=117

6.4.2.8.4. Encephalitis and encephalopathy

During the period of this PSUR, two cases were reported with the MedDRA Preferred Terms encephalitis and/or encephalopathy.

Case **B0649288A** - MedDRA Preferred Terms: Encephalopathy, Altered state of consciousness, Encephalitis, Hypotonia, Hyperreflexia

This case was reported by the Italian Regulatory Authority and described the occurrence of encephalopathy in a 4-month-old female who was vaccinated with unspecified doses of Infanrix hexa™ and Prevenar. Four days after vaccination, the subject experienced aseptic encephalopathy. The subject was hospitalized. The diagnosis was: axial hypotonia with hyperreflexia of patellae. The sensibility could be partially stimulated (to pain). The subject was treated with ceftriaxone, corticosteroids, and antiviral medication. The subject's 24-hour monitoring showed no abnormality (oxygen saturation, heart rate and ECG). NMR and lumbar puncture did not show any abnormality also. Other investigations: PCR was negative to HSV2, EBV, CMV, HSV1, HHV6 and HHV8. At the 13th days of hospitalization the baby began to follow the physiotherapy.

Company comment: A 4-month-old subject experienced hypotonia and hyperreflexia of patellae 4 days after multiple vaccinations. All investigations resulted in normal findings. No symptoms of acute inflammation and/or involvement of central nervous system were reported.

Case **B0678021A** - MedDRA Preferred Terms: Encephalopathy, Decreased eye contact, Psychomotor skills impaired, Speech disorder developmental, Developmental delay, Motor dysfunction, Gait disturbance, Dysstasia, Indifference, Cognitive disorder, Crying, Decreased appetite

This case was reported by the Italian Regulatory Authority and described the occurrence of encephalopathy in a 3-month-old male on the same day as vaccination with Infanrix hexa™ on 16 June 2006. Vaccination history included the 2nd and 3rd doses of Infanrix hexa™ given on 28 July 2006 and 5 February 2007, an unspecified dose of Priorix on 21 November 2007 and an unspecified dose of Prevenar given on 12 March 2008. The subject also developed the following symptoms: inconsolable crying, refusing food, loss of eye contact, slowing psychomotor development each vaccine injection, loss of empathy, lack of language development, delayed walking, regression of motor skills, loss of ability to walk and stand up alone, indifference to the environment and for social interaction, lack of maturation of cognitive functions. At the time of follow-up, the outcome of the event was unresolved.

Company comment: A 4-month-old subject experienced encephalopathy less than 1 day after vaccination. Neither symptoms nor laboratory investigation performed at that time were reported. The subject received further Infanrix hexa™ vaccinations as well as other vaccines: Prevenar, Priorix, but not according to a schedule. The case lacks data on subject medical and family history, results of genetic investigation.

6.4.2.8.5. Hemiparesis and Hemiplegia

During the reporting period one case of hemiparesis and one case of hemiplegia were reported. Both cases **B0666511A** and **D0066195A** were reported together with cerebral haemorrhage. These cases were described in section 6.4.2.8.2 on cerebral haemorrhage.

6.4.2.9. Skin and subcutaneous tissue disorders

6.4.2.9.1. Erythema multiforme

One case of erythema multiforme was received during the reporting period.

Case **B0616513A** – MedDRA Preferred Term: Erythema multiforme

This serious case was reported by a physician via sales representative and described the occurrence of erythema multiforme in a 1-month-old male 2 days after vaccination on 4 December 2009 with unspecified doses of Infanrix hexa™, Prevenar and RotaTeq. At the time of reporting the event was improved.

Company comment: A 1-month-old subject developed erythema multiforme 2 days after multiple vaccinations. This case lacks data on the subject's medical history, data confirming the diagnosis (biopsy), and other possible diagnosis.

6.4.2.9.2. Henoch-Schonlein purpura

One case of Henoch-Schonlein purpura (HSP) was received during the period of this report.

Case **D0067815A** – MedDRA Preferred Terms: Henoch-Schonlein purpura, Pyrexia, Nausea, Vomiting, Decreased appetite, Myalgia, Arthralgia, Erythema nodosum, Malaise, Gait disturbance, Rash, Oedema peripheral, Pain in extremity, Off label use

This serious case was reported by a physician and described the occurrence of Henoch-Schonlein purpura in a 7-year-old male who received on 25 May 2010 the 5th dose of Infanrix hexa™ (right deltoid). There were no concurrent medications, no concurrent medical conditions or any other risk factors. One day after vaccination the subject experienced fever (below 38 deg C), nausea, vomiting and was not eating for 3 days. Nausea and vomiting resolved. Afterward the subject experienced myalgia and arthralgia and, on the left leg, two foci of erythema nodosum. The subject was not feeling well and was limping. The subject experienced rash on right arm with increase to left lower leg and swelling of left ankle joint. The subject was in good general condition with no pain in stomach and no complaints. On the dorsal left lower leg were HSP haemorrhages. The swollen left ankle joint was tender on pressure. At admission to emergency hospital the subject showed no fever. Urine was without pathological findings. On 25 June 2010, HSP was resolved.

Company comment: A 7-year-old subject experienced HSP unspecified time after vaccination with 5th dose of Infanrix hexa™. Infanrix hexa™ is not indicated at this age. Reported gastrointestinal symptoms one day after vaccination could be another plausible cause of this event. The case lacks laboratory data to confirm the diagnosis.

6.4.2.9.3. Petechiae

During the reporting period 31 cases of petechiae were received.

Summary information for the complete set of reports is shown in the below tables. Cases with bolded events terms are also analysed/summarised in the relevant sub-sections of section 6.4 of this PSUR.

6.4.2.9.4. Purpura

During the reporting period 7 cases of purpura have been received.

In cases **B0619820A**, **B0652855A** and **B0656703A** idiopathic thrombocytopenic purpura, thrombocytopenia or thrombocytopenic purpura was reported as well. These cases are described in section 6.4.2.1.1 on thrombocytopenia. The other cases are described below.

Case **B0651934A** – MedDRA Preferred Terms: Vasculitis, Purpura

This serious case was reported by the Italian regulatory authority and described the occurrence of vasculitis and purpura in a 4-month-old female on the same day as vaccination with Infanrix hexa™. The events were resolved.

Case **D0063497A** – MedDRA Preferred Term: Purpura

This non-serious case was reported by a physician, via a sales representative, and described the occurrence of purpura on right leg in an approximately 2.5-month-old female 3 days after vaccination with Infanrix hexa™ (left thigh) and RotaTeq (oral). At the time of reporting the event was improved.

Case **D0067173A** – MedDRA Preferred Terms: Purpura, Pyrexia

This non-serious case was reported by the German regulatory authority and described the occurrence of purpura and fever in a 4-month-old male 10 days after vaccination with a 2nd dose of Infanrix hexa™ (left thigh) and Prevenar (right thigh). Thrombocytopenia was excluded. At the time of reporting the outcome of the events was unspecified.

Case **D0068231A** – MedDRA Preferred Terms: Purpura, Oedema peripheral, Haemostasis

This non-serious case was reported by a physician and described the occurrence of purpura in a 3-month-old female 10 minutes after vaccination who was vaccinated with a 1st dose of Infanrix hexa™ (left upper thigh). Ten days after vaccination the subject experienced fresh large extended purpura (petechia-like of blue colour) below application site, that resolved 2 days later. The subject also developed oedema at back of foot. At the time of reporting all events were resolved. The same case was received via the German regulatory authority. The subject was healthy. The subject experienced fresh extended purpura on left leg below vaccination site over lower leg. Differential diagnose included circular stasis caused by holding or nappy approximately 45 minutes after vaccination. At the time of reporting the events were resolved.

6.4.2.9.5. Subcutaneous nodule

Two non-serious cases of subcutaneous nodule have been received during the reporting period.

Case **B0669691A** – MedDRA Preferred Terms: Hyperaemia, Pyrexia, Injection site pain, Oedema, Subcutaneous nodule, Gait disturbance, Irritability

This case was reported by the Italian regulatory authority and described the occurrence of hyperemia at injection site, fever (38 deg. C), injection site pain, edema, small subcutaneous nodule, difficulty with gait and irritability in a 15-month-old male less than 1 day after vaccination with a 3rd dose of Infanrix hexa™ and Meningitec. At the time of reporting the events were improved.

Case **B0672162A** – MedDRA Preferred Terms: Subcutaneous nodule, Injection site reaction, Pyrexia

This case was reported by the Italian a regulatory authority and described the occurrence of persistent subcutaneous nodule in the right thigh, injection site reaction (local reaction at the legs) and fever (39.5 deg C) for 3 days in a 14-month-old male on the same day as vaccination with a 3rd dose of Infanrix hexa™ and Prevenar (unknown thighs). The subject was treated with paracetamol and ibuprofen. At the time of reporting, the outcome of the events was unspecified.

6.4.2.10. Vascular disorders**6.4.2.10.1. Kawasaki's disease**

Five serious cases of Kawasaki's disease were reported during the period under review and summarised below.

Case **B0616059A** - MedDRA Preferred Terms: Kawasaki's disease, Macrophage activation, Pyrexia, Irritability, Rash erythematous, Oedema peripheral, Pain in extremity, Hepatic function abnormal, Hypoalbuminaemia, Serum ferritin increased, Anaemia, Histiocytosis haematophagic, Rash.

This case was reported by the Italian Regulatory Authority and described the occurrence of Kawasaki disease in a 3-month-old female who was vaccinated with unspecified doses of Infanrix hexa™ and Prevenar on 08 January 2008. One day after vaccination, the subject experienced fever up to 40 C with irritability, erythematous rash on face and legs. The subject started a treatment with antibiotics and was hospitalised. There the subject also experienced bilateral tumefaction with pain at feet. The subject experienced polymorphous rash, peripheral oedema and peripheral erythema. Initial tests showed progressive increase of inflammation index, liver dysfunction, hypoalbuminemia, ferritin increase. An infective etiology of the adverse events was ruled out based on the following tests: EchoCG, cranial and total body CT, CSF analysis, bone marrow analysis and concentration of vanilmandelic and homovanilmandelic acids in urine.

The suspect of Kawasaki's disease was substantiated by the following interventions, performed on 19 February 2008: immunoglobulin infusion and ASA (acetylsalicylic acid) without any improvement of the symptoms. The subject received hemotransfusion due to an anaemia. It was followed by a high-dose therapy with steroids that lead to a rapid improvement in symptoms and clinical data. Steroid therapy was quickly reduced and withdrawn. After 48 hours from the suspension of the steroid therapy, the subject experienced reoccurrence of high fever and was hospitalised. The physicians defined the diagnosis of secondary macrophage activation syndrome in the context of an atypical form of Kawasaki's disease. The subject was treated with high dose steroids and cyclosporine. This led to rapid improvement in symptoms. On 03 March 2008, the subject was discharged from hospital, in a good general condition. Then the subject was monitored periodically, always with good clinical results.

Company comments: The subject experienced fever, irritability and rash one day after multiple vaccinations. Laboratory tests showed inflammation, however no focus was identified. Treatment with immunoglobulin and aspirin was unsuccessful that makes diagnosis of Kawasaki disease doubtful.

Case **B0653827A** – MedDRA Preferred Terms: Kawasaki's disease, Oedema peripheral, Rash maculo-papular, Conjunctivitis, Rash, Cheilitis, Pyrexia

This case was reported by the Italian Regulatory Authority as suspected Kawasaki disease, however during follow-up information received after DLP of this PSUR the Kawasaki disease was not confirmed.

Case **B0657560A** – MedDRA Preferred Terms: Rash maculo-papular, Conjunctivitis, Oedema peripheral, Kawasaki's disease, Pyrexia

This case was reported by the Italian regulatory authority and described the occurrence of maculo-papular exanthema in a 11-month-old male who was vaccinated with unspecified doses of Infanrix hexa™ and Prevenar on 20 April 2010. One day after vaccination, the subject experienced maculo-papular exanthema at back and lower limbs, conjunctivitis, edema of hand, pedal edema and fever (>39 deg.C). Kawasaki disease was considered. The subject was hospitalised and treated with cephalosporins. On 24 April 2010, the events were resolved.

Company comments: The subject experienced fever, rash oedema and conjunctivitis one day after multiple vaccinations. Event resolved 4 days after treatment with antibiotic. Short duration of symptoms (less than 5 days) and response to antibiotic treatment makes reported diagnosis of Kawasaki disease doubtful.

Case **D0066913A** - MedDRA Preferred Terms: Kawasaki's disease, Pyrexia, Interstitial lung disease, Crying, Oligodipsia, Faeces discoloured, Dermatitis diaper, Rash, Conjunctival hyperaemia, Cheilitis, Chapped lips, Skin exfoliation, Anaemia, Thrombocytosis, Hepatic enzyme increased

This case was reported by a physician and described the occurrence of Kawasaki syndrome in a 4-month-old female who was vaccinated with the 1st doses of Infanrix hexa™ and Prevenar. Concomitant medications included antibiotics as needed, as recent family anamnesis included infection of URTI of the sister some days ago. Approximately 3 days post vaccinations, on 07 June 2009, the subject experienced persistent fever up to 40 degC. The subject showed no signs of infection, but CRP increased. The subject was hospitalised for 16 days and diagnosed with Kawasaki syndrome, interstitial pneumonia right, decreased fluid intake and diaper rash. Suspected meningitis was excluded. On admission the subject was in decreased general condition and good nutritional condition. Body temperature was 37.9 degC. The subject was crying and whimpering and showed mild signs of meningeal disorder. The skin was pale and marbled. Laboratory examinations showed increased inflammatory parameters. In combination with clinical signs bacterial infection was suspected and intravenous antibiotic treatment with cefuroxime was started. Thoracic X-rays, performed on 08 and 10 June 2009 showed interstitial pneumonia right lower lobe with spotted extensive pulmonary infiltration due to pneumonia in the lower right pulmonary field. Urinalysis was normal. Blood and CSF cultures were sterile. During course of hospitalisation general condition deteriorated further, laboratory infection parameters worsened and high fever up to 40.3 degC persisted. On 09 June 2009 the subject experienced greenish stools. Test for occult blood was positive one time, but follow-up tests for occult blood were negative. Microbiological stool examinations showed no pathologic findings. Abdominal and cranial sonography was normal. Because of persistent high fever antibiotic treatment was changed to cefotaxime, Certomycin, erythromycin, Unacid, in combination with antimycotic prophylaxis with nystatin. Due to intermittent exanthema, conjunctival injection, lip redness and lip tension (cracked lips), as well as antibiotic resistant fever the subject was diagnosed with possible Kawasaki syndrome. She was treated with normal immunoglobulin and aspirin. Antibiotic treatments were discontinued. Fever resolved and

CONFIDENTIAL

CONFIDENTIAL

general condition improved. The subject showed increased skin exfoliation on hands and feet. Laboratory examinations showed anemia, thrombocytosis and increase in liver values, which were seen within the scope of Kawasaki syndrome and treatment with aspirin. Multiple EchoCG and ECG, performed for controls, showed no conspicuous findings.

Company comments: The reported events are compatible with typical Kawasaki's disease. No coronary abnormalities were observed. Recent URTI in family could not be ruled out as a possible cause of Kawasaki's disease.

Case **D0068409A** - MedDRA Preferred Terms: Kawasaki's disease, Leukocytosis, Meningitis, Gastroenteritis bacterial, Sepsis, Anaemia, Pyrexia, General physical health deterioration, Hyperaesthesia, Crying, Abnormal faeces, Lymphadenopathy, Pain, Acute tonsillitis, Sinus tachycardia, Rash, Chapped lips, Hypotension, Dysplasia, Dry throat, Lip disorder, Conjunctivitis, Hypoalbuminaemia

This case was reported by a physician via the German regulatory authority and described the occurrence of Kawasaki's disease in a 4-month-old subject who was vaccinated with the 2nd doses of Infanrix hexa™ and Prevenar on 09 July 2010. Four days later, the subject was presented to a doctor with high fever without signs of an infection. Laboratory test showed leukocytosis of 19.700. The subject was hospitalised. The subject did not develop cough, rhinitis, diarrhea or vomiting. Fluid intake was well. Maternal concurrent medical condition included rheumatoid arthritis and psoriasis. On admission, general condition was reduced, skin showed no exanthema. Skeleton, eyes, ears, oral cavity, heart, respiration, abdomen and genitals were without pathological findings. Central nervous system was without pathological finding despite of sensitiveness to touch and crying fits. Inflammatory values were increased. Urine test and X-ray of thorax were normal. By differential diagnosis, bacterial gastroenteritis and sepsis was suspected. The subject was treated with cefotaxime for 2 days. The subject developed painful cervical lymph node swelling at right side. There were just solitary stipples at tonsils (angina follicularis). Treatment was changed to clindamycin and cefuroxime for 5 days. Due to recurrent tachycardia during sleep, ECG was performed and showed only sinus tachycardia. EchoCG and sonography of abdomen showed normal results. Values of CRP further increased. The subject was additionally treated with fosfomycin for 3 days. The subject developed small spot exanthema on trunk and dry chapped lips. Fever remained already since 5 days, which could not be resolved by antibiotics. Therefore, Kawasaki's syndrome was diagnosed. The subject was treated with normal immunoglobulin and aspirin. General condition improved fast. Echocardiography excluded coronary ectasia. Thirty hours after treatment with immunoglobulin, the subject's general condition again decreased and second dose of immunoglobulin was administered. The subject was transferred to another hospital for further medical care treatment. First episode of Kawasaki vasculitis on 13 July 2010 and recurrent Kawasaki vasculitis on 20 and 24 July 2010 as well as dysplastic pinna (right more than left sided) was diagnosed. On 04 August 2010, the subject was discharged in good general condition. Fever had not recurred. Recently cardiologic examinations resulted normal. No cardiac manifestations of Kawasaki-syndrome could be identified.

Company comment: The reported events are compatible with typical Kawasaki's disease.

6.5. Follow-Up Data

Relevant follow-up information was received on fatal cases subsequent to their inclusion in PSUR #14. This information was taken into account for the O/E analysis of sudden deaths. CIOMS forms are presented in Appendix 5B.

In case **B0580597A** the autopsy report was received and confirmed SUDI.

In case **B0590738A** cause of death was probably due to underlying conditions.

For cases **B0598135A** and **D0061280A** SIDS was confirmed by autopsy report.

In case **D0061486A** death was due to cardiac failure (probably of genetic origin).

For case **D0062778A** SIDS was not confirmed, cause of death was reported as severe respiratory infection and myocarditis.

No new data has been received for case **B0591078A**.

Of note case **D0038393A** received in 2001 was published in the literature.

7. STUDIES

In line with the Addendum to ICH E2C [2], only studies with findings that have potential impact on product safety information are included in Sections 7.1 and 7.3. These sections do not contain a complete listing of all studies completed or reviewed in the reporting period.

7.1. Newly-Analysed Studies

Three new corporate studies relevant to the safety of Infanrix hexa™ were completed and analysed during the period of this report.

Study #112157 (DTPa-HBV-IPV=Hib-MenC-TT-002 PRI): A phase II, open-label, randomised, multicentre study to evaluate the safety and immunogenicity of GSK Biologicals' DTPa-HBV-IPV/Hib-MenC-TT vaccine co-administered with GSK Biologicals' 10-valent pneumococcal conjugate vaccine in healthy infants when administered as a three-dose primary vaccination course at 2, 3 and 4 months of age. The observed incidence of solicited and unsolicited adverse events was in the same range in the 3 groups, i.e. "Hepta" (candidate heptavalent vaccine), "HexaMnC" (Infanrix hexa™ co-administered with conjugate meningococcal vaccine (Menjugate), and "HexaPn" [Infanrix hexa™ co-administered with conjugate pneumococcal vaccine (Synflorix)]; all the vaccines administered in the study were well tolerated. One SAE (thrombocytopenia) reported for a subject in the Hepta group was considered by the investigator to have a potential causal relationship to vaccination. All serious adverse events reported during the study resolved without sequelae.

Study #110142 (10-PN-PD-DIT-027 PRI): A phase III randomized, single-blind, controlled study to demonstrate the non-inferiority of co-administration of GSK Biological 10-valent pneumococcal conjugate vaccine with Pediacel™ versus co-administration with Infanrix hexa™, when administered to infants as a three-dose primary vaccination course during the first six months of life and as a booster dose at 11-13 months of age. This study was conducted with 3 parallel groups: “10Pn-Hexa” group received 10Pn-PD-DIT and Infanrix hexa™, “10Pn-PDC” group received 10Pn-PD-DIT and Pediacel and “Prev-PDC” group received Prevenar and Pediacel. The incidences of grade 3 solicited local and general adverse events were low in all study groups. The percentage of doses followed by unsolicited adverse events was in the same range in all groups. Grade 3 unsolicited adverse events with causal relationship to vaccination were rarely reported. No fatal SAEs were reported in this study up to the data lock point. Up to the data lock point, SAEs after primary vaccination were reported in 32 subjects (17 subjects in the 10Pn-Hexa group, 5 subjects in the 10Pn-PDC group and 10 subjects in the Prev-PDC group). One of these SAEs reported for a subject in the 10Pn-Hexa group (apparent life threatening event) was assessed by the investigator to be causally related to vaccination.

Study #111654 (10-PN-PD-DIT-048): A phase III, multi-centre, double-blind, randomised study to assess the non-inferiority of a commercial lot of GlaxoSmithKline (GSK) Biologicals 10-valent pneumococcal conjugate (10Pn-PD-DiT) vaccine compared to a clinical phase III vaccine lot, when given as a three-dose primary immunization course. This study was conducted with 2 parallel groups: the “Clin” group received the phase 3 clinical lot of 10Pn-PD-DIT with Infanrix hexa™ or Infanrix-IPV/Hib and HRV, the “Com” group received the commercial lot of 10Pn-PD-DIT with Infanrix hexa™ or Infanrix-IPV/Hib and HRV. All subjects were concomitantly administered a dose of Infanrix hexa™. The following results are supportive of an acceptable safety profile of the clinical phase III:

Unsolicited adverse events:

The percentage of doses followed by at least one unsolicited symptom in the 31-day post-vaccination period was 16.2% in the Clin group and 17.0% in the Com group. The most frequently reported unsolicited AE in each group was upper respiratory tract infection (5.0% in the Clin group and 6.0% in the Com group). The percentage of doses followed by at least one unsolicited symptom considered by the investigator to be causally related to vaccination and the percentage of doses with grade 3 unsolicited AEs in the 31-day post-vaccination period was at most 1.0% in both groups. No grade 3 unsolicited AEs were considered by the investigator to be causally related to vaccination.

Serious adverse events:

No fatal SAEs were reported in this study.

A total of 36 non-fatal SAEs were reported for 25 (5.4%) out of 466 vaccinated subjects: 18 subjects (7.7%) in the Clin group and 7 subjects (3.0%) in the Com group.

No SAEs were considered by the investigator to be causally related to vaccination.

One SAE did not resolve (spinal muscular atrophy) and one SAE (tuberculous meningitis) was still ongoing at the end of this study.

7.2. Targeted Safety Studies

This section provides an update on any planned, ongoing or completed targeted safety studies involving Infanrix hexa™ in the reporting period. Targeted safety studies are those specifically planned or conducted to examine an actual or hypothetical safety concern (Vol 9A, Section 6.3.8.b) in a product marketed anywhere in the world. This includes any GSK-sponsored, and when applicable, GSK-supported pharmacoepidemiology study or clinical trial conducted anywhere in the world with the aim of identifying or quantifying a safety hazard. Although all clinical trials collect safety information as a matter of routine, only those initiated to examine a specific safety concern are considered a targeted safety study.

There are no targeted safety studies for Infanrix hexa.

7.3. Published Safety Studies

Study #217744/100 (DTPa-HBV-IPV-100) is currently in press in Southeast Asian J Trop Med Pub Health 2011; 42(1).

This study was an open, multicentre, post-marketing surveillance (PMS) study to assess the safety and reactogenicity of GlaxoSmithKline Biologicals' DTPa-IPV/Hib vaccine administered at 3 and 4 months of age and DTPa-HBV-IPV/Hib vaccine (Infanrix hexa™) administered at 5 months of age, as primary vaccination course, followed by administration of GSK Biologicals' DTPa-IPV/Hib vaccine at 18 months of age in healthy infants who received hepatitis B vaccine at birth and at one month of age. Both study vaccines were well tolerated and demonstrated a good safety profile. Two SAEs (febrile convulsions and exanthema subitum) were reported by one subject after administration of the booster dose that were considered by the investigator to have causal relationship to the study vaccine. Both events were resolved during the course of the study.

8. OTHER INFORMATION

8.1. Efficacy Related Information

During the period of this report, there were 28 cases where the MedDRA Preferred Terms could potentially correspond to lack of efficacy (LOE) of the pertussis, hepatitis B or Hib component.

8.1.1. Pertussis

Twenty-one cases including the event pertussis were identified during the reporting period. A total of 12 reports were received from Germany, 5 from Ireland, 2 from France, 1 from Italy and 1 from Austria. Seventeen were reported as serious and 4 as non-serious.

From these 21 cases (see below table), 13 were laboratory-confirmed either by positive PCR (n=9) or serological testing (n=4). In the 8 remaining cases, clinical signs and symptoms of pertussis were present (n=2) or no data was available, i.e. pertussis was reported with no further description of the case (n=6).

Table 18 Cases of pertussis during the reporting period

Case ID	Age	Gender	Events PT Comma Sep	Seriousness Fda	Case Outcome	Test
B0603739A	17 Months	Male	Pertussis, Cough, Hypochromasia, Leukocytosis, Regurgitation, Vaccination failure	Serious	Resolved	serology
B0650143A	Infant	Unknown	Pertussis	Not serious	Worse	no data
B0668296A	2 Months	Female	Pertussis, Apnoeic attack, Cough, Gastroesophageal reflux disease, Inflammation	Serious	Improved	clinical
B0674120A*	1 Years		Pertussis, Vaccination failure	Serious	Unknown	PCR
B0675100A*	1 Years		Pertussis, Vaccination failure	Serious	Unknown	PCR
B0675102A*	1 Years		Pertussis, Vaccination failure	Serious	Unknown	PCR
B0675103A*	2 Years		Pertussis, Vaccination failure	Serious	Unknown	PCR
B0675104A*	2 Years		Pertussis, Vaccination failure	Serious	Unknown	PCR
B0675234A	12 Months	Male	Pertussis, Cough, Salivary hypersecretion, Vaccination failure	Serious	Resolved	PCR

CONFIDENTIAL**CONFIDENTIAL**

Case ID	Age	Gender	Events PT Comma Sep	Seriousness Fda	Case Outcome	Test
D0063484A	Child	Female	Pertussis, Vaccination failure, Inappropriate schedule of drug administration	Serious	Resolved	no data
D0063511A	Child	Male	Pertussis, Vaccination failure, Inappropriate schedule of drug administration	Serious	Resolved	no data
D0063525A	Child	Female	Pertussis, Vaccination failure, Inappropriate schedule of drug administration	Serious	Resolved	no data
D0065887A	5 Years	Female	Pertussis, Cough, Vaccination failure	Serious	Resolved	serology
D0066535A	5 Years	Female	Pertussis, Vaccination failure	Serious	Improved	PCR
D0067293A	8 Months	Male	Pertussis, Cough, Bronchitis	Not serious	Unresolved	PCR
D0067933A	4 Months	Female	Pertussis	Not serious	Resolved	clinical
D0067934A	14 Months	Female	Pertussis, Vaccination failure	Serious	Resolved	no data
D0068073A	8 Months	Female	Pertussis, Cough	Not serious	Unknown	PCR
D0068650A	Child		Pertussis, Vaccination failure	Serious	Unknown	no data
D0068825A	10 Years	Male	Pertussis, Vaccination failure	Serious	Unknown	serology
D0069119A	7 Years	Female	Pertussis, Cough, Sneezing, Vaccination failure	Serious	Unknown	serology

*note that these 5 cases were reported in a literature article which describes a community pertussis outbreak that occurred in a small town located in the northwest of Ireland. The extent and development of this outbreak, together with the clinical presentation and also laboratory confirmation supported the hypothesis that most cases were likely to be pertussis.

8.1.2. Diphtheria

During the period covered by this PSUR no case has been identified where the MedDRA Preferred Term could correspond to a lack of effect of the diphtheria component.

8.1.3. Haemophilus influenza type b

During the reporting period 6 cases have been identified that could correspond to LOE of the Hib component.

Case **B0660183A** was reported by a consumer and described the occurrence of *Haemophilus influenza* type b in a male subject of unspecified age at an unspecified time after vaccination with an unspecified dose of Infanrix hexa™.

Case **B0653461A** was reported by a healthcare professional and described the occurrence of *Haemophilus influenzae* serotype b in a 3-year-old subject at an unspecified time after vaccination with Infanrix Hexa™ and Hiberix™. The subject received a 3rd dose of Infanrix hexa™ on 2 October 2007 and an unspecified dose of Hiberix™ on 11 April 2008.

Case **B0653464A** was reported by a healthcare professional and described the occurrence of *Haemophilus influenzae* serotype b in a 7-month-old female 36 days after vaccination with a 3rd dose of Infanrix hexa™. Blood culture was positive after 24 hours incubation. Gram stain was Gram negative bacilli detected in Aerobic bottle and showed growth of *Haemophilus Influenzae* type B. The microbiology report confirmed that the isolate was serotyped as B.

Case **B0675363A** was reported by a healthcare professional and described a 3-year-old male who received a 3rd dose of Infanrix hexa™ on 27 December 2007 and a dose of Hiberix on 18 June 2008 and developed *Haemophilus influenzae* serotype b 3 years after vaccination with Infanrix hexa™ and 2 years after vaccination with Hiberix™. Blood culture showed *Haemophilus influenzae* serotype b.

Case **D0066769A** was reported by a consumer (presumably the subject's mother) and described the occurrence of *Haemophilus influenza* in a 2-year-old female 13 months after the 4th dose of Infanrix hexa™ on 12 January 2009. On 5 March 2010, a test for *Haemophilus influenza* bacteria in throat was positive.

Case **B0677923A** was reported by a physician and described the occurrence of Hib meningitis breakthrough with osteomyelitis, muscle weakness, balance disorder, walking problems, muscular rigidity, fever and vomiting in a 2-year-old male 16 months after vaccination with the 4th dose of Infanrix hexa™. Relevant tests were performed: computerized tomogram of brain showed meningitis and subdural effusion, lumbar puncture (CSF culture) was *Haemophilus influenzae* positive and blood culture which also was *Haemophilus influenzae* positive presented following results: haemoglobin 11.1 g/dl; white blood cells 7.570; neutrophils 66 %; lymphocytes 29.5 %; and thrombocytes 399.000 $10^9/l$. Then white blood cells, C-reactive protein and sedimentation rate was elevated.

8.1.4. Hepatitis B

During the reporting period 1 case has been identified that could correspond to a lack of effect of the hepatitis B component.

Case **D0069123A** was reported by a physician and described the occurrence of negative hepatitis b antibody in a 3-year-old male who was vaccinated with Infanrix hexa™. It was reported that the subject's father (living apart) was hepatitis b positive. In September 2008 the subject received the 4th dose of Infanrix hexa™. Approximately on October 2010, 2 years after vaccination with Infanrix hexa™, a test for Anti-HBs antibody titre was less 10 (hepatitis b antibody negative).

8.1.5. Conclusion of cases of potential lack of efficacy

During the period of this PSUR, 28 cases were identified where the MedDRA Preferred Terms could potentially correspond to a lack of effect of the Hib, pertussis or hepatitis B component.

The table below shows the number of cases and respective reporting frequencies as reported during this PSUR and the previous PSUR periods.

Table 19 Reporting rate of cases that could potentially correspond to lack of efficacy

Disease	PSUR #14		PSUR #15	
	number of cases	reporting rate per 100,000 doses distributed	number of cases	reporting rate per 100,000 doses distributed
Pertussis	24	0.21	21	0.18
Haemophilus influenza	1	0.01	6	0.05
Diphtheria	0	0.00	0	0.00
Hepatitis B	1	0.01	1	0.01

There has been no unusual level of reports of lack of efficacy, which might represent a significant hazard to the treated population.

8.2. Late-breaking information

There has been no new important information received after the data lock point.

8.3. EU Risk Management Plan

There is no specific risk management plan in place for Infanrix hexa.

8.4. Benefit Risk Analysis

During the PSUR reporting period, no separate risk-benefit analysis has been conducted.

9. OVERALL SAFETY EVALUATION

9.1. Signal Management

GSK employs a routine, pro-active process for identifying safety signals¹ with three main components:

Ongoing awareness and review of important individual cases, including all reports with a fatal outcome.

Systematic, regular and proactive review of aggregate safety data. This includes trend analysis to detect increased frequency of reporting and quantitative methodologies to detect drug interactions and signals in overdose/medication errors, paediatrics and the elderly.

Systematic, regular review of the literature.

A holistic approach is used so that all relevant data sources are interrogated when evaluating safety signals e.g. external sources, clinical studies, epidemiological studies, pre-clinical information.

All signals identified are evaluated; however, priority is given for serious events, particularly events reported with disproportionately high frequency, DMEs², and events that if found to be causally related to the vaccine could significantly affect the benefit-risk profile.

Following evaluation of the signal, appropriate action is agreed. The options include continuing routine proactive pharmacovigilance, defining further work to better understand the risk, or recommendation of a label change and/or amendment to the Risk Management Plan (RMP).

GSK is able to detect issues of potential concern promptly and, where appropriate, communicate them expeditiously to regulators outside the PSUR process. Actions taken on these issues are then reflected in the PSUR to ensure information is communicated appropriately to all regulatory authorities.

¹A safety signal is defined as a report or reports of an event with an unknown causal relationship to treatment that is recognised as worthy of further exploration and continued surveillance (CIOMS VI).

²Designated Medical Events: medically important events that are generally associated with drug toxicity.

Table 20 presents the reporting frequency of the 10 most frequently reported events for **Infanrix hexa™** arising from spontaneous reporting including regulatory and consumer reports. For this analysis both serious and non-serious events reported were taken into account, from launch up to the data lock point of this safety update report. Listed events are in bold.

Table 20 Overview of the 10 most frequently spontaneously reported events for **Infanrix hexa™. Events in bold are listed in CSI version 10.**

Event SOC	Event PT	Number Of Events ¹	Reporting frequency per 100,000 doses distributed
General disorders and administration site conditions	Pyrexia	3560	5.87
Nervous system disorders	Crying	1113	1.84
General disorders and administration site conditions	Injection site erythema	975	1.61
General disorders and administration site conditions	Injection site swelling	826	1.36
Injury, poisoning and procedural complications	Inappropriate schedule of drug administration	589	0.97
Nervous system disorders	Hypotonia	529	0.87
Vascular disorders	Pallor	461	0.76
Skin and subcutaneous tissue disorders	Erythema	446	0.74
General disorders and administration site conditions	Injection site induration	420	0.69
General disorders and administration site conditions	Injection site reaction	416	0.69

1. Including regulatory non serious and consumer reports, but excluding clinical trial cases.

All these top 10 events were reported with a frequency between 0.69 to 5.87 per 100,000 doses distributed.

Since the last PSUR the top 10 events has not significantly changed in the reporting frequency except for inappropriate schedule of drug administration, which is now part of the top 10 events. This is mainly related to cases received from France reported via a solicited interview or market research (see section on medication errors).

9.2. Adverse events of interest

The cumulative count of an event since launch is provided in the following sections is based on the count of MedDRA PTs from cases originating from spontaneous reporting (including non-medically verified and regulatory non-serious cases).

9.2.1. Cases with a fatal outcome

During the period covered by this report 14 fatal cases were identified.

9.2.1.1. Cases of Sudden Death (SD)

Ten cases suggestive of sudden deaths (sudden infant death syndrome: SIDS and sudden unexpected death in infancy: SUDI) were identified during the period covered by this PSUR. A cumulative review of Sudden Death since launch has been performed. Follow-up information is taken into account.

Table 21 shows the number of cases as reported during the different PSUR periods linked to the patient exposure of each period.

Table 21 Reporting rate of SD since launch per PSUR period

PSUR #	period	time period	number of doses sold doses	number of SD as reported in the different PSURs	reporting rate per 100,000 doses distributed
15	23oct09-22oct10	1Y	11981722	10	0.08
14	23oct08-22oct09	1Y	11496552	12	0.10
13	23oct07-22oct08	1Y	10067611	7	0.07
12	23oct06-22oct07	1Y	8621066	6	0.07
11	23oct05-22oct06	1Y	7166964	9	0.13
10	23apr05-22oct05	6M	2282686	2	0.09
9*	23oct00-22apr05	4 1/2Y	9681894	18	0.19
8	23apr04-22oct04	6M	1386298	1	0.07
7	23oct03-22apr04	6M	1246906	5	0.40
6	23apr03-22oct03	6M	1247422	4	0.32
5	23oct02-22apr03	6M	1041975	1	0.10
4	23apr02-22oct02	6M	998814	0	0.00
3	23oct01-22apr02	6M	772137	1	0.13
2	23apr01-22oct01	6M	1050000	1	0.10
1	23oct00-22apr01	6M	430000	0	0.00

*Note that this PSUR covers 4 years and a half and comprises data since launch

This table shows that the reporting frequency of SD is relatively stable over time.

Observed/Expected Analysis of SD

INTRODUCTION

Regarding the PSUR#14 sent in December 2009, EMA requested that *“The MAH should try to collect relevant and recent data of background incidences rates of sudden death in other European countries.”*

METHODS

1- Literature research

In order to collect relevant and recent data, a literature review of sudden death or sudden infant death was performed for Europe. The search of the literature was made in PubMed and Embase using simultaneously the key words “sudden infant death” or “sudden death”, “incidence rate” and “Europe” without restriction on dates. However for SIDS, only publications after 1990’s were selected due to the effect of „Back to Sleep” campaign performed in several European countries. Publications were limited to those published in French and English languages. The bibliographies of identified studies and reviews were searched to identify additional studies of interest. The German Federal Statistical Office was also consulted on line. The search was made in November 2010.

2- Observed Expected Analysis

To estimate the expected numbers, the incidence rate of SID was considered homogenous within each age (ie. over 1st or 2d year of life); therefore the expected number over any day was linearly extrapolated (ie. 1/365) from the prevalence per birth cohort.

The number of cases expected to occur within a predetermined risk period following vaccination (Ne) for children under 1 year of age and those between 1 and 2 years of age is derived from the following formula:

$$Ne = Inc \times Nbc \times RiskPeriod \times \alpha$$

where

Inc = the incidence of the disease in the first or second year of life

0.454 per 1,000 live births for < 1 year olds

0.062 per 1,000 live births for 1<2 year olds

CONFIDENTIAL

CONFIDENTIAL

Nbc = the number of doses of vaccine sold since launch (assumption: proportion of adverse events by age is representative for the actual age distribution at vaccination).

$Risk\ Period$ = adjustment from a predetermined risk period (Days/365)

α = healthy vaccinee correction factor (taken here to be 0.8 based on various case-control studies of SIDS or SUID).

RESULT

Literature research

The tables below present the background incidence rate of Sudden Death or Infant Sudden Death in Europe. The incidence rates of Sudden Death in the table 22 are not all directly comparable since they may refer to different age groups and/or different periods.

Table 22 Incidence rate of Sudden Death per 100,000 person-years

Country/Population	Time period	Age (years)	Number of Sudden Deaths	Incidence Rate (/100,000 py)	Author
Sweden. 6-year retrospective study; necropsy records. Population aged of 1-20 years	1974-1979	1- 20	31	1.15	Molander, 1982

Observed/Expected Analysis of Sudden Deaths (SD)

Given the attention that has been given to the occurrence of sudden deaths in children in the second year of life within 14 days of the administration of hexavalent vaccines, the Company evaluated whether the number of sudden deaths reported in this age group exceeded the number one could expect to occur by coincidence.

Since the distribution of the age at which subjects are vaccinated is unknown, the Company assumed that the proportion of adverse events by age is representative for the actual age distribution at vaccination. It can thus be estimated that 90.6% of all recipients of Infanrix hexa™ were in their first year of life, and 9.4% were in their second year of life. Therefore the number of doses (since launch) was estimated to be 54,927,729 and 5,698,904 respectively. Given that Germany is the main country where Infanrix hexa™ doses are distributed (close to 30% only in Germany); It was assumed that the incidence of sudden death observed in Germany is representative for the entire population of Infanrix hexa™ recipients (German Federal Bureau of Statistics, Statistisches Bundesamt; incidence rate in 1st year of life: 0.454/1,000 live births; second year: 0.062/1,000 live births, data 2008). A healthy vaccinee correction factor (taken here to be 0.8 based on various case-control studies of SIDS or SUID) was applied.

The results of this analysis are present in the below table that shows the number of sudden deaths that could be expected to occur by chance within a range of days post-vaccination.

CONFIDENTIAL

CONFIDENTIAL

Table 24 Cumulative number of O/E cases SD following Infanrix hexa™, first and second year of life, Oct 00 - Dec 10

Time since vaccination	1st year of life		2nd year of life	
	Observed	Expected	Observed	Expected
Less than 1 day	10	54.7	1	0.8
1 day	20	109.3	2	1.5
2 days	33	164.0	3	2.3
3 days	42	218.6	3	3.1
4 days	49	273.3	3	3.9
5 days	50	327.9	3	4.6
6 days	50	382.6	3	5.4
7 days	51	437.3	4	6.2
8 days	52	491.9	5	7.0
9 days	54	546.6	5	7.7
13 days	54	765.2	6	10.8
15 days	55	874.5	6	12.4
16 days	56	929.2	6	13.2
18 days	57	1038.5	6	14.7
19 days	58	1093.1	6	15.5

This analysis shows that the number of sudden death cases reported within 19 days of Infanrix hexa™ vaccination is below the number of cases expected for this time period in children under 2 years of age except when death occurred during the first three days after vaccination in the second year of life where the observed death number is almost equal to the number expected.

The Company will continue to monitor these cases and their reporting frequencies.

Limitations

There are several limitations for Observed/Expected analyses, and several levels of uncertainty. The major factors affecting O/E analyses are related to:

- Underreporting, reporting biases, and incomplete case details.
- Uncertainty on the number of subjects actually vaccinated.
- No age stratification within the two age groups.

9.2.2. Other adverse events of interest

9.2.2.1. Blood and lymphatic system disorders

9.2.2.1.1. *Idiopathic thrombocytopenic purpura, Thrombocytopenia, Thrombocytopenic purpura*

During the period of this PSUR eleven serious cases including the event idiopathic thrombocytopenic purpura (n=6), thrombocytopenia (n=6) or thrombocytopenic purpura (n=1) were identified. The immune character of the events was confirmed only in one case of warm type haemolytic anaemia. In two cases B0619820A and D0067175A negative re-challenge was observed.

Since launch, 63 cases of autoimmune thrombocytopenia, idiopathic thrombocytopenic purpura, thrombocytopenia and thrombocytopenic purpura have been received corresponding to a reporting frequency of 0.10 per 100,000 doses distributed.

Thrombocytopenia is a listed event.

The Company will continue monitoring this event closely.

9.2.2.2. Cardiac disorders

9.2.2.2.1. *Cyanosis*

Fifty cases including the MedDRA Preferred Term cyanosis were identified during the period of this report. Most cases (45/50) were reported in association with a concurrent condition likely to have caused cyanosis such as convulsions, HHE, hypotonia, hypertonia, apnoea, dyspnoea, ALTE, and syncope. In the remaining 5 cases no clear pattern of events suggestive of a clinical condition or syndrome could be identified.

Since launch, 224 cases have been received corresponding to a reporting frequency of 0.37 per 100,000 doses distributed.

The information received in these cases does not provide evidence of a specific safety signal.

9.2.2.3. Eye disorders

9.2.2.3.1. *Gaze palsy*

Twenty four cases with the MedDRA Preferred Term gaze palsy were received during the period of this report. It concerned 15 males, 9 females, aged between 1 month and 2 years (median: 5.5 months). Time to onset ranged between less than 1 day to 7 days (median: less than 1 day). Outcome was reported as resolved in 19 cases, unresolved in 1 case and unknown in 4 cases. In all cases this event was reported in association with concurrent events, mostly convulsions (17).

The information received in these cases does not provide evidence of a specific safety signal.

9.2.2.3.2. Retinal haemorrhage

Two cases with the MedDRA Preferred Term retinal haemorrhage were reported during this PSUR period. In one case B0636708A child maltreatment syndrome was suspected. In the second case B0677766A the event was reported in the context of status epilepticus.

The information received in these cases does not provide evidence of a safety signal.

9.2.2.4. Gastrointestinal disorders

9.2.2.4.1. Diarrhoea haemorrhagic, Haematochezia, Melaena, Rectal haemorrhage

During the period of this report, 10 cases were received with one the following MedDRA Preferred Terms: diarrhoea haemorrhagic (n=1), haematochezia (n=7), melaena (n=1) and/or rectal haemorrhage (n=3). In case B0619820A rectal haemorrhage was reported as a symptom of ITP. In tree cases (B0643201A, B0651961A and B0663295A) haematochezia was reported in association with intussusception. In cases B0615474A and B0624719A, the subjects developed concurrent acute gastroenteritis or oesophagitis. In cases D0068600A and D0068909A investigations were normal and the events resolved spontaneously. In cases B0605572A and B0671786A insufficient data was provided for medical assessment.

The information received in these cases does not provide evidence of a specific safety signal.

9.2.2.4.2. Intussusception

During the period of this report, four cases with the MedDRA Preferred Term intussusception have been received. In one case the symptoms likely occurred 20 minutes after vaccination, in 2 cases the event was observed from 2.5 to 7 months after vaccination and likely related to gastroenteritis, and in one case, intussusception was suspected but not confirmed.

The information received in these cases does not provide evidence of a specific safety signal.

9.2.2.5. General disorders and administration site conditions

9.2.2.5.1. Abscess sterile, Injection site abscess sterile and vaccination site abscess sterile

Five cases with the MedDRA Preferred Term abscess sterile as well as two cases coded with the MedDRA Preferred Terms injection site abscess sterile or vaccination site abscess sterile have been received during this reporting period. Cases D0063315A, D0063315B and D0063315C described recurrent sterile abscess at injection sites after vaccination with Infanrix hexa™ in the same subject. In case D0068815A, the subject experienced the event within one year after vaccination with sterile secretion. In case D0068941A, the subject experienced injection site reaction one month after vaccination and sonography revealed two structures that have been interpreted as possible granuloma and possible abscess. In two cases D0067836A and D0069205A, abscesses were drained and revealed pus that were not analyzed.

Since launch, 31 cases of abscess sterile, injection site abscess sterile and vaccination site abscess sterile have been received corresponding to a reporting frequency of 0.05 per 100,000 doses distributed.

The information received in these cases does not provide evidence of a specific safety signal.

9.2.2.5.2. Injection site necrosis

One case with the MedDRA Preferred Term injection site necrosis was identified during the period covered by this report. The event was observed 2 days after vaccination after removal of injection site blister.

Since launch, 8 cases of injection site necrosis have been received corresponding to a reporting frequency of 0.01 per 100,000 doses distributed.

The information received in these cases does not provide evidence of a specific safety signal.

9.2.2.5.3. Injection site nodule and Nodule

Twenty-six cases with the MedDRA Preferred Term injection site nodule and 3 cases with the MedDRA Preferred Term nodule have been received during the period of this report, corresponding to a reporting frequency of 0.24 per 100,000 doses distributed.

Three cases met the criteria for „regulatory“ seriousness. The majority of cases lack data for adequate assessment e.g. specific site of injection when concurrent vaccines are given, and/or time to onset and/or time to outcome.

Since launch, 136 cases of injection site nodule and nodule have been received corresponding to a reporting frequency of 0.22 per 100,000 doses distributed.

The Company will continue monitoring this event closely.

9.2.2.6. Immune system disorders

9.2.2.6.1. Anaphylactic reaction and anaphylactic shock

Four cases with the MedDRA Preferred Term anaphylactic reaction and/or anaphylactic shock were identified during the period covered by this report. In three cases the subjects received multiple vaccinations and in the fourth case the subject had multiple concurrent therapies with unspecified start date.

Only one of these (D0068761A) met sufficient criteria in order to confirm true anaphylaxis (Anaphylaxis: Case definition and guidelines for data collection, analysis, and presentation of immunization safety data The Brighton Collaboration Anaphylaxis Working Group. Vaccine 25 (2007) 5675-5684).

Since launch, 17 cases of anaphylactic reaction and anaphylactic shock have been received corresponding to a reporting frequency of 0.03 per 100,000 doses distributed. The company will continue to monitor cases of anaphylactic reaction and anaphylactic shock.

9.2.2.7. Infections and infestations

9.2.2.7.1. Abscess, Abscess limb, Incision site abscess, Injection site abscess, Vaccination site abscess

During the reporting period, 17 cases were received including one of the following MedDRA Preferred Terms: abscess (n=4), abscess limb (n=1), incision site abscess (n=5), injection site abscess (n=10) and/or vaccination site abscess (n=2).

These cases feature 11 males, 5 females and 1 unknown gender with a median age of 4 months (range: from 6 weeks to 2 years, n=16). At time of reporting, events resolved in 7 cases, resolved with sequelae in 3 cases, improved in 1 case, were unknown in 6 cases. Only in one case D0068928A the causing agent of injection site abscess *Staphylococcal aureus* was found. In case B0545354A *Staphylococcal septicaemia* was detected after the 3rd attempt of abscess drainage. The abscess was treated with antibiotics in 9 cases (B0607303A, B0609130A, B0622903A, B0639606A, B0641879A, B0680202A, D0066818A, D0068798A, D0068798B) and surgery or drainage in 2 cases (B0661002A, B0600650A).

There is no concentration of these cases by batch, supportive of a manufacturing issue.

Since launch, 116 cases have been received corresponding to a reporting frequency of 0.19 per 100,000 doses distributed.

The Company will continue to monitor all cases of abscess and injection site abscess.

9.2.2.7.2. Cellulitis and Injection site cellulitis

During the period under review 7 cases with the MedDRA Preferred Term “Cellulitis” and 1 case with the MedDRA Preferred Term “Injection site cellulitis” were received. In all described cases, the subjects were aged between 17 months and 3 years and received their booster dose of Infanrix hexa™. Six of them received antibiotics. In six cases, no causing agent of cellulitis was identified. In case D0067880A, cellulitis was confirmed by unspecified serology. In case B0675146A, a co-suspect vaccine was involved with unknown injection sites for both vaccines. Bacteriological tests were negative at the reaction site. Blood culture was positive for coagulase negative staphylococcus 8 days after vaccines administration.

Since launch, 35 cases have been received corresponding to a reporting frequency of 0.06 per 100,000 doses distributed.

These reports do not constitute a safety signal.

9.2.2.7.3. Meningitis, Meningitis aseptic, Meningitis pneumococcal

During the period under review, 3 cases were received with the MedDRA Preferred Terms “Meningitis” (n=1), “Meningitis aseptic” (n=1) and “Meningitis pneumococcal” (n=1). In case D0068409A, meningitis was suspected but the final diagnosis was Kawasaki’s disease. In case B0651993A of aseptic meningitis no data confirming this event were reported. In the last case D0066195A, a 4-month-old subject experienced pneumococcal meningitis, confirmed CSF results.

These reports do not constitute a safety signal.

9.2.2.7.4. Sepsis

Four cases were reported with the MedDRA Preferred Term sepsis during the period of this report. None of these 4 cases provide sufficient information to confirm sepsis by bacteriaemia.

Since launch, 28 cases have been received corresponding to a reporting frequency of 0.05 per 100,000 doses distributed.

These reports do not constitute a safety signal.

9.2.2.8. Musculoskeletal and connective tissue disorders

9.2.2.8.1. Nodule on extremity

During the reporting period, two cases were reported with the MedDRA Preferred Term nodule on extremity. One case lacks information on the Infanrix hexa™ injection site, in the other case, the event was reported together with abscess.

These reports do not constitute a safety signal.

9.2.2.9. Nervous system disorders

9.2.2.9.1. Seizures

Atonic seizures, Clonic convulsion, Clonus, Convulsion, Convulsions local, Febrile convulsion, Grand mal convulsion, Myoclonus, Partial seizures, Tonic convulsion

During the reporting period, 117 individual case reports, 82 febrile and 35 afebrile convulsions, were received including one of the following MedDRA Preferred Terms: atonic seizures (n=1), clonic convulsion (n=1), clonus (n=1), convulsion (n=55), convulsions local (n=1), febrile convulsion (n=54), grand mal convulsion (n=18), myoclonus (n=4), partial seizures (n=3) and/or tonic convulsion (n=3).

Subject age was provided in 114 reports included in the analysis and ranged from 1 month to 3 years with a median of 5 months. Subject gender was provided in 112 reports and included 54 males and 58 females. TTO was provided in 108 reports and ranged from less than 1 day to 3 weeks (median: less than 1 day).

The reporting frequency and the pattern of the cases did not deviate from the last PSUR reporting period.

Convulsions (with or without) fever is included in the current Core Safety Information for Infanrix hexa™

These cases do not raise a safety signal.

Epilepsy, Infantile spasms, Petit mal epilepsy, Status epilepticus

During this reporting period 11 cases of epilepsy, 4 cases of petit mal epilepsy, 2 cases of infantile spasm and 4 cases of status epilepticus were reported.

In only 4 cases out of the 13 reports of epilepsy and petit mal epilepsy diagnosis of epilepsy can be considered as confirmed. In case B0645066A a family origin of epilepsy has also to be also considered. In case B0657965A epilepsy was considered as a part of metabolic disturbance. In case D0068399A, it was reported that diagnosis was confirmed by several examination, but data were not provided. In case (B0664846A), the subject was diagnosed with epilepsy before vaccination.

In three of the four cases of status epilepticus EEG was reported as normal and in one case the diagnosis of shaken baby was considered.

These cases do not raise a safety signal.

9.2.2.9.2. Cerebral atrophy

During the period of this report, 1 case with the MedDRA Preferred Term cerebral atrophy was identified. In this case (D0067158A) the subject was diagnosed with cerebral atrophy on NMR and suspected Watanabe epilepsy after multiple vaccinations. The reported subject's conditions (postpartum hemorrhagic gastritis, hyperbilirubinemia, postpartum anemia, treated with transfusion and suspected epilepsy) might have contributed to an observed psychomotor retardation.

Since launch 6 cases of cerebral atrophy have been received, corresponding to a reporting frequency of 0.01 per 100,000 doses distributed.

This case does not raise a safety signal.

9.2.2.9.3. Cerebral haemorrhage

Two reports received during this PSUR period with the MedDRA Preferred Terms cerebral haemorrhage.

In one case B0666511A the subject experienced haemorrhage one day after multiple vaccinations. The case lacks information on investigation of other causes of haemorrhage like infection diseases, coagulation disorders. The second case D0066195 reported this event in the context of pneumococcal meningitis.

Since launch, 5 cases have been received with cerebral haemorrhage, corresponding to a reporting frequency of 0.01 per 100,000 doses distributed.

These cases do not raise a safety signal.

9.2.2.9.4. Encephalitis and Encephalopathy

During the period of this PSUR, two cases case were reported with the MedDRA Preferred Terms encephalitis and/or encephalopathy.

In one case the subject was hospitalized due to suspicion of meningitis 4 days after multiple vaccinations. However, all investigations resulted in normal findings. Reported data are insufficient to support a diagnosis of encephalitis. In the second case (B0678021A) the subject experienced progressive psychomotor retardation, but no information on cause investigation was reported.

Since launch, 29 cases of encephalitis and/or encephalopathy have been received, corresponding to a reporting frequency of 0.05 per 100,000 doses distributed.

The Company will continue to monitor important neurological events, including encephalitis and encephalopathy.

9.2.2.10. Skin and subcutaneous tissue disorders

9.2.2.10.1. Erythema multiforme

During the period of this report, one case with the MedDRA Preferred Term erythema multiforme has been identified. No data confirming this diagnosis were provided.

The information received in this case does not constitute a safety signal.

Since launch, 13 cases were received corresponding to a reporting frequency of 0.02 per 100,000 doses distributed.

The Company will continue to monitor cases of erythema multiforme.

9.2.2.10.2. Henoch-Schonlein purpura

During the period of this report, one case with the MedDRA Preferred Term Henoch-Schonlein purpura was received.

The case lacks details on laboratory confirmation of the diagnosis.

Since launch, 5 cases were received corresponding to a reporting frequency of 0.01 per 100,000 doses distributed.

The Company will continue to monitor cases of Henoch-Schonlein purpura.

9.2.2.10.3. Petechiae

During the period covered by this report 31 cases were identified with the MedDRA Preferred Term petechiae.

In 26 cases the subjects received multiple vaccinations. In 8 cases petechiae were observed together with purpura, thrombocytopenia, and/or IPT. In 4 cases petechiae were reported as a single event. In the other cases, petechiae were mainly associated with other signs and symptoms, and give no indication of a specific safety signal.

Since launch, 132 cases were received corresponding to a reporting frequency of 0.22 per 100,000 doses distributed.

The Company will continue to monitor cases of petechiae.

CONFIDENTIAL

CONFIDENTIAL

9.2.2.10.4. Purpura

During the period of this report, seven cases with the MedDRA Preferred Term purpura were received.

In cases B0619820A, B0652855A and B0656703A idiopathic thrombocytopenic purpura, thrombocytopenia or thrombocytopenic purpura was reported as well. In cases B0651934A and D0068231A purpura was observed within on the same day as vaccination and resolved spontaneously without treatment. Cases D0063497A and D0067173A lack information for medical assessment.

The information received in these cases does not constitute a specific safety signal.

Since launch, 28 cases were received corresponding to a reporting frequency of 0.05 per 100,000 doses distributed.

The company will continue to monitor cases of purpura.

9.2.2.10.5. Subcutaneous nodule

Two non-serious cases with the MedDRA Preferred Term “Subcutaneous nodule” have been received during the reporting period. In both cases the event was observed shortly after vaccination in the context of other injection site reaction.

The information received in these cases does not constitute a specific safety signal.

9.2.2.11. Vascular disorders

9.2.2.11.1. Kawasaki’s disease

Five serious cases with the MedDRA Preferred Term “Kawasaki’s disease” were reported during the period under review. In one case B0653827A the event was ruled out according to the follow-up information. In two cases B0616059A and B0657560A reported information is incompatible with the diagnosis of Kawasaki’s disease. The remaining two cases D0066913A and D0068409A are compatible with typical Kawasaki’s disease, but none of the subjects develop cardiac complications.

Based on the individual case history assessment no safety signal was identified.

Since launch, 18 cases were received corresponding to a reporting frequency of 0.03 per 100,000 doses distributed.

The information received in these cases does not provide evidence of a specific safety signal.

9.3. Areas of Regulatory Interest

Areas of regulatory interest (specifically Drug Interactions, Overdose and Medication Errors, Abuse Potential, Pregnancy and Lactation, Use in Children) routinely monitored throughout the product lifecycle and during the period of the PSUR are presented below. Note that non-medically verified reports and non-serious reports received from regulatory authorities are included in these analyses.

9.3.1. Drug interactions

No cases of potential drug interactions have been received during the reporting period.

Most of the spontaneous cases reported during the period of this report include co-administration with other vaccines (mostly pneumococcal vaccines). Vaccination with pneumococcal vaccines is standard practice in the countries where most reports originated (Germany and Italy).

No relevant findings were noticed as regards the co-administration profile of the vaccine. No cluster of events suggestive of potential interaction was found.

No new important safety information regarding drug interactions has been identified in the time period.

9.3.2. Overdose and Medication Errors

A total of 687 cases of potential overdose and/or reports of medication error have been received during the reporting period. Non-medically verified and regulatory non-serious cases are included in this analysis.

In view of the varying ways in which reports of overdose and medication error are described and coded, there is often much overlap between these concepts.

9.3.2.1. Overdose

“Overdose” is defined as more than the recommended dose of vaccine administered at the same occasion (either two vaccine doses administered too soon one after each other or two vaccines with overlapping components accidentally co-administered.)

A total of 17 non-serious cases of overdose and accidental overdose have been identified in the current time period.

Adverse events were reported in 6 cases: irritability in cases B0649576A and B0677762A; gait disturbance, joint stiffness, pyrexia and injection site reaction in case B0651926A; pyrexia in cases B0663536A and B0675106A and pyrexia and restlessness in case B0666873A.

No new important safety information regarding overdose has been identified during the time period.

9.3.2.2. Medication Errors

In addition to cases with overdose and accidental overdose, 670 cases involving medication errors have been identified in the current time period. From these reports, 638 were reported with no adverse events and 32 with adverse events. An overview per category of maladministration is presented in the below table. Note that a case can contain more than one PT related to maladministration.

Table 25 Overview per category of maladministration

Category of maladministration (MedDRA PT)	Number Of Events
Inappropriate schedule of drug administration	342
Wrong drug administered	227
Wrong technique in drug usage process	90
Incorrect storage of drug	31
Incorrect dose administered	25
Underdose	23
Incorrect product storage	17
Off label use	13
Overdose	13
Drug administration error	11
Incorrect route of drug administration	10
Expired drug administered	7
Accidental overdose	5
Drug dispensing error	2
Accidental exposure	1
Drug administered at inappropriate site	1
Medication error	1

Eighty-two percent of the medication errors cases were reported from France (551 cases). The majority of the cases concerned mainly the following:

- Inappropriate schedule of drug administration: cases where Infanrix hexa™ administration was reported not following the locally recommended vaccination schedule (most of the time the interval between two consecutive doses was too short or the subject was outside the normal range of the vaccination schedule).
- Wrong drug administered: another vaccine should have been administered.

CONFIDENTIAL

CONFIDENTIAL

Of these 551 cases of medication errors reported from France, the majority were reported via a solicited interview or market research.

Indeed, on the request of the CEPS (Comité économique des produits de santé, French authority in charge of drug price in France) and following the reimbursement of Infanrix hexa™ in France, two studies were requested by the authorities in order to evaluate the evolution of hepatitis B vaccinal status in infants and to evaluate the acceptability of hepatitis B vaccine.

One study consists of interviewing parents on vaccination (PopCorn) or physicians (Praline). These studies are handled by the French pharmacoepidemiological department and are subcontracted to a company called Kappa Santé. These studies are run on 3 years.

The other study is a market study (Vaccinoscopia) handled by the marketing department and subcontracted to a company called Institut des mamans. The objective is to obtain information about vaccinal coverage, age of vaccination, compliance with the French vaccinal recommendations. The Institut des mamans has a panel of mothers who answered via internet to questions on vaccination of their children.

Adverse events were reported in 32 cases. Cases with bolded event terms are also analysed/summarised in the relevant sub-sections of section 6.4 of this PSUR.

No new important safety information regarding medication errors has been identified during the time period.

9.3.3. Abuse or misuse

Not applicable to vaccines.

9.3.4. Pregnancy and Lactation

9.3.4.1. Pregnancy

All cases involving a pregnant patient are included. In addition, the search strategy includes a broad selection of MedDRA PTs suggesting exposure *in utero* or via breast feeding or indicative of birth defects (e.g. congenital or hereditary disorders). Thus the search retrieves cases where pregnancy outcome is abnormal, normal or unknown. Cases involving females over 60 years of age and adult males (where the case was not reported as a partner pregnancy) have been excluded. Note that this search does not include the entire SMQ for „Adverse Pregnancy Outcome/Reproductive Toxicity (incl neonatal disorders)“; furthermore, it includes some terms that are not in the SMQ.

One case possibly related to administration during pregnancy has been received during the reporting period and since launch.

CONFIDENTIAL

CONFIDENTIAL

Case **B0606306A** was reported by a physician and was a prospective report of pregnancy in a 28-year-old female who was vaccinated with Infanrix hexa™ while she was pregnant (23 weeks of amenorrhea). Upon follow-up received on 04 October 2010: nothing in particular occurred during pregnancy and delivery, for the mother and the baby.

No new important safety information regarding use in pregnancy has been identified during the time period.

9.3.4.2. Lactation

No cases have been received during the reporting period where Infanrix hexa was known to have been given to lactating mothers.

9.3.5. Special Patient Groups

No new important safety information related to use in the children, elderly or organ impaired patients has been identified in the reporting period.

9.3.6. Effects of long-term treatment

Not applicable to vaccines.

9.3.7. Patient/Consumer and other non-healthcare professional reports.

The events of interest described in section 6.5 within the PSUR review period include all cases (irrespective of source, seriousness and listedness). Non-healthcare professional reports are therefore discussed in section 6.5. Separate Line Listings and Summary Tabulations are provided as appendices for consumer reports as per guideline E2C(R1).

10. CONCLUSION

From the review of data received during the reporting period and presented in this PSUR, it has been concluded that the safety profile of Infanrix hexa™ is adequately reflected in the Reference Safety Information.

No further amendments to RSI are considered necessary at this time.

The benefit/risk profile of Infanrix hexa™ continues to be favourable.

The Company will continue to monitor all cases of thrombocytopenia, injection site nodule and nodule, anaphylaxis, abscess and injection site abscess, important neurological events including encephalitis and encephalopathy, erythema multiforme, Henoch-Schonlein purpura, petechiae and purpura.

GLOBAL PRESCRIBER INFORMATION

TITLE

Combined diphtheria-tetanus-acellular pertussis, hepatitis B, enhanced inactivated polio vaccine and *Haemophilus influenzae* type b vaccine.

SCOPE

Trade Name(s)

Infanrix hexa

Formulation, Strength and Device* (*if appropriate)

Infanrix hexa contains diphtheria toxoid, tetanus toxoid, three purified pertussis antigens [pertussis toxoid (PT), filamentous hemagglutinin (FHA) and pertactin (PRN; 69 kiloDalton outer membrane protein)] and the purified major surface antigen (HBsAg) of the hepatitis B virus (HBV) and purified polyribosyl-ribitol-phosphate capsular polysaccharide (PRP) of *Haemophilus influenzae* type b (Hib), covalently bound to tetanus toxoid, adsorbed onto aluminium salts. It also contains three types of inactivated polio viruses (type 1: Mahoney strain; type 2: MEF-1 strain; type 3: Saukett strain).

The tetanus and diphtheria toxoids are obtained by formaldehyde treatment of purified *Corynebacterium diphtheriae* and *Clostridium tetani* toxins. The acellular pertussis vaccine components are obtained by extraction and purification from phase I *Bordetella pertussis* cultures, followed by irreversible detoxification of the pertussis toxin by glutaraldehyde and formaldehyde treatment, and formaldehyde treatment of FHA and PRN. The diphtheria toxoid, tetanus toxoid and acellular pertussis components are adsorbed onto aluminium salts. The DTPa-HBV-IPV components are formulated in saline.

The surface antigen of the HBV is produced by culture of genetically-engineered yeast cells (*Saccharomyces cerevisiae*) which carry the gene coding for the major surface antigen of the HBV. This HBsAg expressed in yeast cells is purified by several physico-chemical steps. The HBsAg assembles spontaneously, in the absence of chemical treatment, into spherical particles of 20 nm in average diameter containing non-glycosylated HBsAg polypeptide and a lipid matrix consisting mainly of phospholipids. Extensive tests have demonstrated that these particles display the characteristic properties of the natural HBsAg.

The three polioviruses are cultivated on a continuous VERO cell line, purified and inactivated with formaldehyde.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 009
Version Date: 23-Nov-07

The Hib polysaccharide is prepared from Hib, strain 20,752 and after activation with cyanogen bromide and derivatisation with an adipic hydrazide spacer is coupled to tetanus toxoid via carbodiimide condensation. After purification the conjugate is adsorbed on aluminium salt, and then lyophilised in the presence of lactose as stabiliser.

Infanrix hexa meets the World Health Organisation requirements for manufacture of biological substances, of diphtheria, tetanus, pertussis and combined vaccines, of hepatitis B vaccines made by recombinant DNA techniques, of inactivated poliomyelitis vaccines and of Hib conjugate vaccines.

A 0.5 ml dose of the vaccine contains not less than 30 IU of adsorbed diphtheria toxoid, not less than 40 IU of adsorbed tetanus toxoid, 25 mcg of adsorbed PT, 25 mcg of adsorbed FHA, 8 mcg of adsorbed pertactin, 10 mcg of adsorbed recombinant HBsAg protein, 40 D-antigen units of type 1 (Mahoney), 8 D-antigen units of type 2 (MEF-1) and 32 D-antigen units of type 3 (Saukett) of the polio virus. It also contains 10 mcg of adsorbed purified capsular polysaccharide of Hib (PRP) covalently bound to 20-40 mcg tetanus toxoid (T).

Version Number: 009
Version Date: 23-Nov-07

Formaldehyde

Neomycin sulphate

Polymyxin B sulphate

CLINICAL INFORMATION [1]

Indications

Infanrix hexa is indicated for primary and booster vaccination of infants against diphtheria, tetanus, pertussis, hepatitis B, poliomyelitis and *Haemophilus influenzae* type b.

Dosage and Administration

- Primary vaccination

The primary vaccination schedule consists of three doses of 0.5 ml (such as 2, 3, 4 months; 3, 4, 5 months; 2, 4, 6 months) or two doses (such as 3, 5 months). There should be an interval of at least 1 month between doses. The Expanded Program on Immunisation schedule (at 6, 10, 14 weeks of age) may only be used if a dose of hepatitis B vaccine has been given at birth.

Locally established immunoprophylactic measures against hepatitis B should be maintained. Where a dose of hepatitis B vaccine is given at birth, Infanrix hexa can be used as a replacement for supplementary doses of hepatitis B vaccine from the age of 6 weeks. If a second dose of hepatitis B vaccine is required before this age, monovalent hepatitis B vaccine should be used.

- Booster vaccination:

After a vaccination with 2 doses (e.g. 3, 5 months) of Infanrix hexa a booster dose must be given at least 6 months after the last priming dose, preferably between 11 and 13 months of age.

After vaccination with 3 doses (e.g. 2, 3, 4 months; 3, 4, 5 months; 2, 4, 6 months) of Infanrix hexa a booster dose may be given at least 6 months after the last priming dose and preferably before 18 months of age.

Booster doses should be given in accordance with the official recommendations.

Infanrix hexa can be considered for the booster if the composition is in accordance with the official recommendations.

CONFIDENTIAL

CONFIDENTIAL

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 009
Version Date: 23-Nov-07

Other combinations of antigens have been studied in clinical trials following primary vaccination with Infanrix hexa and may be used for a booster dose: diphtheria, tetanus, acellular pertussis (DTPa), diphtheria, tetanus, acellular pertussis, *Haemophilus influenzae* type b (DTPa/Hib), diphtheria, tetanus, acellular pertussis, inactivated poliomyelitis, *Haemophilus influenzae* type b (DTPa-IPV/Hib) and diphtheria, tetanus, acellular pertussis, hepatitis B, inactivated poliomyelitis, *Haemophilus influenzae* type b (DTPa-HBV-IPV/Hib).

Infanrix hexa is for deep intramuscular injection.

Contraindications

Hypersensitivity to the active substances or to any of the excipients or residues. (see Excipients and Residues)

Hypersensitivity after previous administration of diphtheria, tetanus, pertussis, hepatitis B, polio or Hib vaccines.

Infanrix hexa is contra-indicated if the child has experienced an encephalopathy of unknown aetiology, occurring within 7 days following previous vaccination with pertussis containing vaccine. In these circumstances pertussis vaccination should be discontinued and the vaccination course should be continued with diphtheria-tetanus, hepatitis B, inactivated polio and Hib vaccines.

Warnings and Precautions

As with other vaccines, administration of Infanrix hexa should be postponed in subjects suffering from acute severe febrile illness. The presence of a minor infection is not a contra-indication.

Vaccination should be preceded by a review of the medical history (especially with regard to previous vaccination and possible occurrence of undesirable events) and a clinical examination.

If any of the following events are known to have occurred in temporal relation to receipt of pertussis-containing vaccine, the decision to give further doses of pertussis-containing vaccines should be carefully considered :

Temperature of $\geq 40.0^{\circ}\text{C}$ within 48 hours, not due to another identifiable cause.

Collapse or shock-like state (hypotonic-hyporesponsiveness episode) within 48 hours of vaccination.

Persistent, inconsolable crying lasting ≥ 3 hours, occurring within 48 hours of vaccination.

CONFIDENTIAL

CONFIDENTIAL

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 009
Version Date: 23-Nov-07

Convulsions with or without fever, occurring within 3 days of vaccination.

There may be circumstances, such as a high incidence of pertussis, when the potential benefits outweigh possible risks.

In children with progressive neurological disorders, including infantile spasms, uncontrolled epilepsy or progressive encephalopathy, it is better to defer pertussis (Pa or Pw) immunization until the condition is corrected or stable. However, the decision to give pertussis vaccine must be made on an individual basis after careful consideration of the risks and benefits. As with all injectable vaccines, appropriate medical treatment and supervision should always be readily available in case of a rare anaphylactic event following the administration of the vaccine.

Infanrix hexa should be administered with caution to subjects with thrombocytopenia or a bleeding disorder since bleeding may occur following an intramuscular administration to these subjects.

Infanrix hexa should under no circumstances be administered intravascularly or intradermally.

Infanrix hexa contains traces of neomycin and polymyxin. The vaccine should be used with caution in patients with known hypersensitivity to one of these antibiotics.

Infanrix hexa will not prevent disease caused by pathogens other than *Corynebacterium diphtheriae*, *Clostridium tetani*, *Bordetella pertussis*, hepatitis B virus, poliovirus or *Haemophilus influenzae* type b. However, it can be expected that hepatitis D will be prevented by immunisation as hepatitis D (caused by the delta agent) does not occur in the absence of hepatitis B infection.

A protective immune response may not be elicited in all vaccinees (see section Pharmacodynamic effects).

A history of febrile convulsions, a family history of convulsions or Sudden Infant Death Syndrome (SIDS) do not constitute contraindications for the use of Infanrix hexa. Vaccinees with a history of febrile convulsions should be closely followed up as such adverse events may occur within 2 to 3 days post vaccination.

Human Immunodeficiency Virus (HIV) infection is not considered as a contra-indication. The expected immunological response may not be obtained after vaccination of immunosuppressed patients.

Since the HIB capsular polysaccharide antigen is excreted in the urine a positive urine test can be observed within 1-2 weeks following vaccination. Other tests should be performed in order to confirm HIB infection during this period.

CONFIDENTIAL

CONFIDENTIAL

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 009
Version Date: 23-Nov-07

Limited data in 169 premature infants indicate that *Infanrix hexa* can be given to premature children. However, a lower immune response may be observed and the level of clinical protection remains unknown.

The potential risk of apnoea and the need for respiratory monitoring for 48-72h should be considered when administering the primary immunization series to very premature infants (born < 28 weeks of gestation) and particularly for those with a previous history of respiratory immaturity. As the benefit of vaccination is high in this group of infants, vaccination should not be withheld or delayed.

Interactions

There are insufficient data with regard to the efficacy and safety of simultaneous administration of *Infanrix hexa* and Measles-Mumps-Rubella vaccine to allow any recommendation to be made.

Data on concomitant administration of *Infanrix hexa* with Prevenar (pneumococcal saccharide conjugated vaccine, adsorbed) have shown no clinically relevant interference in the antibody response to each of the individual antigens when given as a 3 dose primary vaccination.

However, high incidence of fever (> 39.5°C) was reported in infants receiving *Infanrix Hexa* and Prevenar compared to infants receiving the hexavalent vaccine alone.

Antipyretic treatment should be initiated according to local treatment guidelines.

As with other vaccines it may be expected that in patients receiving immunosuppressive therapy, an adequate response may not be achieved.

Pregnancy and Lactation

Pregnancy

As *Infanrix hexa* is not intended for use in adults, adequate human data on use during pregnancy and adequate animal reproduction studies are not available.

Lactation

As *Infanrix hexa* is not intended for use in adults, adequate human data on use during lactation and adequate animal reproduction studies are not available.

Ability to perform tasks that require judgement, motor or cognitive skills

The vaccine is unlikely to produce an effect on the ability to drive and use machines.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 009
Version Date: 23-Nov-07

Adverse Reactions

- Clinical trials:

The safety profile presented below is based on data from more than 16,000 subjects.

As has been observed for DTPa and DTPa-containing combinations, an increase in local reactogenicity and fever was reported after booster vaccination with Infanrix hexa with respect to the primary course.

Frequencies per dose are defined as follows:

Very common: $\geq 10\%$

Common: $\geq 1\%$ and $< 10\%$

Uncommon: $\geq 0.1\%$ and $< 1\%$

Rare: $\geq 0.01\%$ and $< 0.1\%$

Very rare: $< 0.01\%$

Infections and infestations

Uncommon: upper respiratory tract infection

Metabolism and nutrition disorders

Very common: appetite lost

Psychiatric disorders:

Very common: irritability, crying abnormal, restlessness

Common: nervousness

Nervous system disorders:

Uncommon: somnolence

Very rare: convulsions (with or without fever)

Respiratory, thoracic and mediastinal disorders

Uncommon: cough*

Rare: bronchitis

----------------------------	------	------

† cut-off accepted as indicative of protection

As the immune response to pertussis antigens following *Infanrix hexa* administration is equivalent to that of *Infanrix™*, the protective efficacy of the two vaccines is expected to be equivalent.

The protective efficacy of the pertussis component of *Infanrix™* against WHO-defined typical pertussis (≥ 21 days of paroxysmal cough) was demonstrated in:

- a prospective blinded household contact study performed in Germany (3, 4, 5 months schedule). Based on data collected from secondary contacts in households where there was an index case with typical pertussis, the protective efficacy of the vaccine was 88.7%.
- a NIH sponsored efficacy study performed in Italy (2, 4, 6 months schedule). The vaccine efficacy was found to be 84%. In a follow-up of the same cohort, the efficacy was confirmed up to 60 months after completion of primary vaccination without administration of a booster dose of pertussis.

Results of long term follow-up in Sweden demonstrate that acellular pertussis vaccines are highly efficacious in infants when administered according to the 3 and 5 months primary vaccination schedule, with a booster dose administered at approximately 12 months. However, data indicate that protection against pertussis may be waning at 7-8 years of age. This suggests that a second booster dose of pertussis vaccine is warranted in children aged 5-7 years who have previously been vaccinated following this schedule.

Protective immunity against hepatitis B has been shown to persist for at least 3.5 years in more than 90% of children administered four doses of *Infanrix hexa*. Antibody levels were not different from what was observed in a parallel cohort administered monovalent hepatitis B vaccine.

The effectiveness of the GlaxoSmithKline Biologicals™ Hib component (when combined with DTPa, or DTPa-IPV or DTPa-HBV-IPV) has been and continues to be investigated via an extensive post-marketing surveillance study conducted in Germany. Over a 4.5 year follow-up period, the effectiveness of DTPa/Hib or DTPa-IPV/Hib vaccines was 96.7% for a full primary series and 98.5% for a booster dose (irrespective of priming). Over a three year follow-up period, the effectiveness of hexavalent vaccines was 92.8% for a full primary series and 100% for a booster dose.

NON-CLINICAL INFORMATION

Preclinical data reveal no special hazard for humans based on conventional studies of safety, specific toxicity, repeated dose toxicity and compatibility of ingredients.

PHARMACEUTICAL INFORMATION

Shelf-Life

The expiry date of the vaccine is indicated on the label and packaging. The date for last use corresponds to the first day of the month mentioned.

The shelf-life is 36 months.

Storage

Infanrix hexa should be stored at +2°C to +8°C. Protect from light.

During transport, recommended conditions of storage must be respected.

The DTPa-HBV-IPV suspension and the reconstituted vaccine must not be frozen.
Discard if it has been frozen.

Nature and Contents of Container

The DTPa-HBV-IPV component is presented as a turbid white suspension in a syringe. Upon storage, a white deposit and clear supernatant can be observed.

The lyophilised Hib vaccine is presented as a white pellet in a glass vial or in a glass vial with Bioset®.

The vials and syringes are made of neutral glass type I, which conforms to European Pharmacopoeia Requirements.

Vial and syringe with or without needles in packs of 1, 10, 20 and 50.

Vial with Bioset® and syringe with or without needle in packs of 1, 10, 20 and 50

Incompatibilities

Infanrix hexa should not be mixed with other vaccines in the same syringe.

Use and Handling

Wording for vial and syringe

CONFIDENTIAL

CONFIDENTIAL

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 009
Version Date: 23-Nov-07

The DTPa-HBV-IPV suspension should be well shaken in order to obtain a homogeneous turbid white suspension. The DTPa-HBV-IPV suspension and the Hib powder should be inspected visually for any foreign particulate matter and/or variation of physical aspect. In the event of either being observed, discard the container.

The vaccine is reconstituted by adding the contents of the syringe to the vial containing the Hib powder. It is good clinical practice to only inject a vaccine when it has reached room temperature. In addition, a vial at room temperature ensures sufficient elasticity of the rubber closure to minimise any coring of rubber particles. To achieve this, the vial should be kept at room temperature (25 ± 3 °C) for at least five minutes before connecting the syringe and reconstituting the vaccine.

The reconstituted vaccine presents as a slightly more cloudy suspension than the liquid component alone. This is normal and does not impair the performance of the vaccine. In the event of other variation being observed, discard the vaccine.

After reconstitution, the vaccine should be injected promptly. However the vaccine may be kept for up to 8 hours at room temperature (21°C).

Wording for vial with Bioset® and syringe

The DTPa-HBV-IPV suspension should be well shaken in order to obtain a homogeneous turbid white suspension. The DTPa-HBV-IPV suspension and the Hib powder should be inspected visually for any foreign particulate matter and/or variation of physical aspect. In the event of either being observed, discard the container.

To achieve this, the vial should be kept at room temperature (25 ± 3 °C) for at least five minutes before connecting the syringe and reconstituting the vaccine.

1. For reconstitution, remove while twisting the cover from the vial with the Bioset® cap containing the Hib component and remove the cap from the syringe.
2. Connect the syringe (without the needle) onto the vial with the Bioset® cap and push it downwards – without pushing on the stopper - until syringe „clicks“ into position.
3. Inject the liquid contained in the syringe into the vial and shake carefully until the Hib powder is completely dissolved.
4. Aspirate the reconstituted vaccine back into syringe and then unscrew the syringe from the empty vial with the Bioset® cap.
5. Affix a needle on the syringe for administering the vaccine.

GLOBAL PATIENT LEAFLET

Read all of this leaflet carefully before your child starts receiving this vaccine.

- Keep this leaflet until your child has finished the complete vaccination course. You may need to read it again.
- If you have any further questions, ask your doctor or your pharmacist.
- This vaccine has been prescribed for your child. Do not pass it on to others.
- If any of the side effects gets serious, or if you notice any side effects not listed in this leaflet, please tell your doctor or pharmacist.

TITLE

Diphtheria (D), tetanus (T), pertussis (acellular, component) (Pa), hepatitis B (rDNA) (HBV), poliomyelitis (inactivated) (IPV) and *Haemophilus* type b (HIB) conjugate vaccine (adsorbed).

Trade Name of the product

Infanrix hexa, Powder and suspension for suspension for injection

Formulation and strength

Infanrix hexa contains immunogenic agents that will stimulate an immune response to diphtheria, tetanus, pertussis, hepatitis B, poliomyelitis and *Haemophilus* type b. Infanrix hexa is presented as a powder and a suspension for injection (1 dose of 0.5 ml) to be reconstituted before vaccination.

Excipients

The other ingredients in Infanrix hexa are:

Hib powder: lactose anhydrous

DTPa-HBV-IPV suspension: sodium chloride (NaCl), aluminium hydroxide, aluminium phosphate and water for injections, Medium 199 (as stabilizer including amino acids, mineral salt and vitamins).

Residues (optional)

Potassium chloride, disodium phosphate, monopotassium phosphate, polysorbate 20 and 80, glycine, formaldehyde, neomycin sulphate, polymyxin B sulphate

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 009
Version Date: 23-Nov-07

WHAT INFANRIX HEXA IS AND WHAT IT IS USED FOR

The diphtheria, tetanus, acellular pertussis, hepatitis B, inactivated poliomyelitis (DTPa-HBV-IPV) component is a white, slightly milky liquid presented in a prefilled syringe (0.5 ml).

The Hib component is a white powder presented in a glass vial or in a glass vial with Bioset®.

Both components must be mixed together before your child receives the vaccine. The mixed appearance is a white, slightly milky liquid.

Infanrix hexa is available in packs of 1, 10, 20 and 50 with or without needles.

Infanrix hexa is a vaccine used in children to prevent six diseases: diphtheria, tetanus (lockjaw), pertussis (whooping cough), hepatitis B, poliomyelitis (Polio) and *Haemophilus influenzae* type b. The vaccine works by causing the body to produce its own protection (antibodies) against these diseases.

- **Diphtheria:** Diphtheria mainly affects the airways and sometimes the skin. Generally the airways become inflamed (swollen) causing severe breathing difficulties and sometimes suffocation. The bacteria also release a toxin (poison), which can cause nerve damage, heart problems, and even death.
- **Tetanus (Lockjaw):** Tetanus bacteria enter the body through cuts, scratches or wounds in the skin. Wounds that are especially prone to infection are burns, fractures, deep wounds or wounds contaminated with soil, dust, horse manure/dung or wood splinters. The bacteria release a toxin (poison), which can cause muscle stiffness, painful muscle spasms, fits and even death. The muscle spasms can be strong enough to cause bone fractures of the spine.
- **Pertussis (Whooping cough):** Pertussis is a highly infectious illness. The disease affects the airways causing severe spells of coughing that may interfere with normal breathing. The coughing is often accompanied by a “whooping” sound, hence the common name “whooping cough”. The cough may last for 1-2 months or longer. Pertussis can also cause ear infections, bronchitis which may last a long time, pneumonia, fits, brain damage and even death.
- **Hepatitis B:** Hepatitis B is caused by the hepatitis B virus. It causes the liver to become swollen (inflamed). The virus is found in body fluids such as blood, semen, vaginal secretions, or saliva (spit) of infected people.
- **Poliomyelitis (Polio):** Poliomyelitis, sometimes called simply “polio” is a viral infection that can have variable effects. Often it causes only a mild illness but in some people it causes permanent damage or even death. In its severest form, polio infection causes paralysis of the muscles (muscles cannot move), including those

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 009
Version Date: 23-Nov-07

muscles needed for breathing and walking. The limbs affected by the disease may be painfully deformed.

- **Haemophilus influenzae** type b (Hib): Hib infection most frequently causes brain inflammation (swelling). There will be some type of serious complications such as: mental retardation, cerebral palsy, deafness, epilepsy or partial blindness. Hib infection also causes inflammation of the throat. It occasionally causes death by suffocation. Less commonly, the bacteria can also infect the blood, heart, lungs, bones, joints, and tissues of the eyes and mouth.

Vaccination is the best way to protect against these diseases. None of the components in the vaccine are infectious.

BEFORE YOUR CHILD RECEIVES INFANRIX HEXA

Infanrix hexa should not be given:

- if your child has previously had any allergic reaction to Infanrix hexa, or any ingredient contained in this vaccine. The active substances and other ingredients in Infanrix hexa are listed at the beginning of the leaflet. Signs of an allergic reaction may include itchy skin rash, shortness of breath and swelling of the face or tongue.
- if your child has previously had an allergic reaction to any vaccine against diphtheria, tetanus, pertussis (whooping cough), hepatitis B, poliomyelitis or *Haemophilus influenzae* type b diseases.
- if your child experienced problems of the nervous system within 7 days after previous vaccination with a vaccine against pertussis (whooping cough) disease.

Take special care with Infanrix hexa:

- if your child has a severe infection with a high temperature (over 38°C). A minor infection such as a cold should not be a problem, but talk to your doctor first.
- if after previously having Infanrix hexa or another vaccine against pertussis (whooping cough) disease, your child had any problems, especially:
 - ◆ A high temperature (over 40°C) within 48 hours of vaccination
 - ◆ A collapse or shock-like state within 48 hours of vaccination
 - ◆ Persistent crying lasting 3 hours or more within 48 hours of vaccination
 - ◆ Seizures/fits with or without a high temperature within 3 days of vaccination
- if your child is suffering from neurological disorders, including infantile spasms, uncontrolled epilepsy or progressive encephalopathy (disease of brain)
- if your child has a bleeding problem or bruises easily
- if your child has a tendency to seizures/fits due to a fever, or if there is a history in the family of this
- if your child has breathing difficulties, please contact your doctor. This may be more common in the first three days following vaccination if your child is born prematurely (before or at 28 weeks of pregnancy).

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 009
Version Date: 23-Nov-07

Using other medicines or vaccines

Please tell your doctor if your child is taking or has recently taken any other medicines, including medicines obtained without a prescription or has recently received any other vaccine.

Important information about some of the ingredients of Infanrix hexa

Please tell your doctor if your child has had an allergic reaction to neomycin or polymyxin (antibiotics).

HOW INFANRIX HEXA IS GIVEN

Your child will receive a total of three or two injections with an interval of at least one month between each one. Each injection is given on a separate visit. You will be informed by the doctor or nurse when you should come back for subsequent injections.

If additional injections or “booster” are necessary, the doctor will tell you.

If your child misses a scheduled injection, talk to your doctor and arrange another visit.

Make sure your child finishes the complete vaccination course of three or two injections. If not, your child may not be fully protected against the diseases.

The doctor will give Infanrix hexa as an injection into the muscle.

POSSIBLE SIDE EFFECTS

Like all medicines, Infanrix hexa can cause side effects, although not everybody gets them.

Side effects that may occur are the following:

- ◆ **Very common** (more than 1 in 10 doses of vaccine):
 - Loss of appetite
 - Restlessness, unusual crying, irritability
 - Pain, redness and swelling at the injection site
 - Fever ($\geq 38^{\circ}\text{C}$)
 - Tiredness
- ◆ **Common** (up to 1 in 10 doses of vaccine):
 - Nervousness
 - Vomiting, diarrhoea
 - Fever ($> 39.5^{\circ}\text{C}$)
 - Hard lump at the injection site
 - Itching

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 009
Version Date: 23-Nov-07

-
- ◆ **Uncommon** (up to 1 in 100 doses of vaccine):
 - Upper respiratory tract infection
 - Sleepiness
 - Cough
 - ◆ **Rare** (up to 1 in 1000 doses of vaccine):
 - Bronchitis
 - Rash
 - ◆ **Very Rare** (less than 1 in 10.000 doses of vaccine):
Side effects occurred very rarely during clinical trials or routine use of the vaccine or with other diphtheria, tetanus and pertussis containing vaccines include:
 - As with all injectable vaccines, there is an extremely small risk of severe allergic reactions. These can be recognised by:
 - Itchy rash of the hands and feet
 - Swelling of the eyes and face
 - Difficulty in breathing or swallowing
 These reactions will usually occur before leaving the doctor's surgery.
However, if your child gets any of these symptoms you should contact a doctor urgently.
 - Swollen glands in the neck, armpit or groin
 - Bleeding or bruising more easily than normal
 - Collapse or periods of unconsciousness, lack of awareness, seizures or fits (with or without fever) which usually occur within 2 to 3 days after vaccination
 - Temporarily stopping breathing
 - Swelling of the entire injected limb
 - Blister at the injection site
 - Hives

If your child gets side effects

If any of the side effects gets serious, or if you notice any side effects not listed in this leaflet, please tell your doctor or pharmacist.

HOW TO STORE INFANRIX HEXA

Store in a refrigerator (2°C – 8°C).

Store in the original package in order to protect from light.

Do not freeze. Freezing destroys the vaccine.

Keep out of the reach and sight of children.

Do not use Infanrix hexa after the expiry date which is stated on the carton. The expiry date refers to the last day of that month.

GLOBAL PRESCRIBER INFORMATION

TITLE

Combined diphtheria-tetanus-acellular pertussis, hepatitis B, enhanced inactivated polio vaccine and *Haemophilus influenzae* type b vaccine.

SCOPE

Trade Name(s)

Infanrix hexa

Formulation and Strength

Powder and suspension for suspension for injection.

1 dose (0.5 ml) contains:

Diphtheria toxoid ¹	not less than 30 International units
Tetanus toxoid ¹	not less than 40 International units
<i>Bordetella pertussis</i> antigens	
Pertussis toxoid ¹	25 micrograms
Filamentous Haemagglutinin ¹	25 micrograms
Pertactin ¹	8 micrograms
Hepatitis B surface antigen ^{2,3}	10 micrograms
Poliovirus (inactivated)	
type 1 (Mahoney strain) ⁴	40 D-antigen unit
type 2 (MEF-1 strain) ⁴	8 D-antigen unit
type 3 (Saukett strain) ⁴	32 D-antigen unit
<i>Haemophilus influenzae</i> type b polysaccharide (polyribosylribitol phosphate) ³	10 micrograms
conjugated to tetanus toxoid as carrier protein	20 - 40 micrograms
¹ adsorbed on aluminium hydroxide, hydrated (Al(OH) ₃)	0.5 milligrams Al ³⁺
² produced in yeast cells (<i>Saccharomyces cerevisiae</i>) by recombinant DNA technology	
³ adsorbed on aluminium phosphate (AlPO ₄)	0.32 milligrams Al ³⁺
⁴ propagated in VERO cells	

The DTPa-HBV-IPV component is presented as a turbid white suspension. Upon storage, a white deposit and clear supernatant can be observed.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

The Hib component is presented as a white powder.

Excipients

It is mandatory for country product information to include both the complete list of excipients for all locally marketed presentations, and any locally imposed excipient warning statements.

Lactose

Sodium chloride (NaCl)

Medium 199 (as stabilizer including amino acids, mineral salts and vitamins)

Water for injections

Residues

Potassium chloride

Disodium phosphate

Monopotassium phosphate

Polysorbate 20 and 80

Glycine

Formaldehyde

Neomycin sulphate

Polymyxin B sulphate

CLINICAL INFORMATION

Indications

Infanrix hexa is indicated for primary and booster vaccination of infants against diphtheria, tetanus, pertussis, hepatitis B, poliomyelitis and *Haemophilus influenzae* type b.

Dosage and Administration

Posology

- **Primary vaccination**

The primary vaccination schedule consists of three doses of 0.5 ml (e.g. 2, 3, 4 months; 3, 4, 5 months; 2, 4, 6 months) or two doses (e.g. 3, 5 months). There should be an interval

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

of at least 1 month between doses. The Expanded Program on Immunisation schedule (at 6, 10, 14 weeks of age) may only be used if a dose of hepatitis B vaccine has been given at birth.

Locally established immunoprophylactic measures against hepatitis B should be maintained. Where a dose of hepatitis B vaccine is given at birth, Infanrix hexa can be used as a replacement for supplementary doses of hepatitis B vaccine from the age of 6 weeks. If a second dose of hepatitis B vaccine is required before this age, monovalent hepatitis B vaccine should be used.

- **Booster vaccination**

After a vaccination with 2 doses (e.g. 3, 5 months) of Infanrix hexa a booster dose must be given at least 6 months after the last priming dose, preferably between 11 and 13 months of age.

After vaccination with 3 doses (e.g. 2, 3, 4 months; 3, 4, 5 months; 2, 4, 6 months) of Infanrix hexa a booster dose may be given at least 6 months after the last priming dose and preferably before 18 months of age.

Booster doses should be given in accordance with the official recommendations.

Infanrix hexa can be considered for the booster if the composition is in accordance with the official recommendations.

Other combinations of antigens have been studied in clinical trials following primary vaccination with Infanrix hexa and may be used for a booster dose: diphtheria, tetanus, acellular pertussis (DTPa), diphtheria, tetanus, acellular pertussis, *Haemophilus influenzae* type b (DTPa+Hib), diphtheria, tetanus, acellular pertussis, inactivated poliomyelitis, *Haemophilus influenzae* type b (DTPa-IPV+Hib) and diphtheria, tetanus, acellular pertussis, hepatitis B, inactivated poliomyelitis, *Haemophilus influenzae* type b (DTPa-HBV-IPV+Hib).

Method of administration

Infanrix hexa is for deep intramuscular injection.

Contraindications

Hypersensitivity to the active substances or to any of the excipients or residues (see *Formulation and Strength, Excipients and Residues*).

Hypersensitivity after previous administration of diphtheria, tetanus, pertussis, hepatitis B, polio or Hib vaccines.

Infanrix hexa is contraindicated if the child has experienced an encephalopathy of unknown aetiology, occurring within 7 days following previous vaccination with

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

pertussis containing vaccine. In these circumstances pertussis vaccination should be discontinued and the vaccination course should be continued with diphtheria-tetanus, hepatitis B, inactivated polio and Hib vaccines.

Warnings and Precautions

As with other vaccines, administration of Infanrix hexa should be **postponed** in subjects suffering from **acute severe febrile illness**. The presence of a minor infection is not a contra-indication.

Vaccination should be preceded by a review of the medical history (especially with regard to previous vaccination and possible occurrence of undesirable events) and a clinical examination.

If any of the following events are known to have occurred in temporal relation to receipt of pertussis-containing vaccine, the decision to give further doses of pertussis-containing vaccines should be carefully considered:

- Temperature of $\geq 40.0^{\circ}\text{C}$ within 48 hours, not due to another identifiable cause.
- Collapse or shock-like state (hypotonic-hyporesponsiveness episode) within 48 hours of vaccination.
- Persistent, inconsolable crying lasting ≥ 3 hours, occurring within 48 hours of vaccination.
- Convulsions with or without fever, occurring within 3 days of vaccination.

There may be circumstances, such as a high incidence of pertussis, when the potential benefits outweigh possible risks.

In children with progressive neurological disorders, including infantile spasms, uncontrolled epilepsy or progressive encephalopathy, it is better to defer pertussis (Pa or Pw) immunization until the condition is corrected or stable. However, the decision to give pertussis vaccine must be made on an individual basis after careful consideration of the risks and benefits.

As with all injectable vaccines, appropriate medical treatment and supervision should always be readily available in case of a rare anaphylactic event following the administration of the vaccine.

Infanrix hexa should be administered with caution to subjects with thrombocytopenia or a bleeding disorder since bleeding may occur following an intramuscular administration to these subjects.

Infanrix hexa should under no circumstances be administered intravascularly or intradermally.

Infanrix hexa contains traces of neomycin and polymyxin. The vaccine should be used with caution in patients with known hypersensitivity to one of these antibiotics.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

Infanrix hexa will not prevent disease caused by pathogens other than *Corynebacterium diphtheriae*, *Clostridium tetani*, *Bordetella pertussis*, hepatitis B virus, poliovirus or *Haemophilus influenzae* type b. However, it can be expected that hepatitis D will be prevented by immunisation as hepatitis D (caused by the delta agent) does not occur in the absence of hepatitis B infection.

A protective immune response may not be elicited in all vaccinees (see *Pharmacodynamic Effects*).

A history of febrile convulsions, a family history of convulsions or Sudden Infant Death Syndrome (SIDS) do not constitute contraindications for the use of Infanrix hexa. Vaccinees with a history of febrile convulsions should be closely followed up as such adverse events may occur within 2 to 3 days post vaccination.

Human Immunodeficiency Virus (HIV) infection is not considered as a contra-indication. The expected immunological response may not be obtained after vaccination of immunosuppressed patients.

Since the Hib capsular polysaccharide antigen is excreted in the urine a positive urine test can be observed within 1-2 weeks following vaccination. Other tests should be performed in order to confirm Hib infection during this period.

Limited data in 169 premature infants indicate that Infanrix hexa can be given to premature children. However, a lower immune response may be observed and the level of clinical protection remains unknown.

The potential risk of apnoea and the need for respiratory monitoring for 48-72h should be considered when administering the primary immunization series to very premature infants (born ≤ 28 weeks of gestation) and particularly for those with a previous history of respiratory immaturity. As the benefit of vaccination is high in this group of infants, vaccination should not be withheld or delayed.

Syncope (fainting) can occur following, or even before, any vaccination as a psychogenic response to the needle injection. It is important that procedures are in place to avoid injury from faints.

Interactions

There are insufficient data with regard to the efficacy and safety of simultaneous administration of Infanrix hexa and Measles-Mumps-Rubella vaccine to allow any recommendation to be made.

Data on concomitant administration of Infanrix hexa with Prevenar (pneumococcal saccharide conjugated vaccine, adsorbed) have shown no clinically relevant interference in the antibody response to each of the individual antigens when given as a 3 dose primary vaccination.

However, high incidence of fever ($> 39.5^{\circ}\text{C}$) was reported in infants receiving Infanrix hexa and Prevenar compared to infants receiving the hexavalent vaccine alone.

Antipyretic treatment should be initiated according to local treatment guidelines.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

As with other vaccines, it may be expected that in patients receiving immunosuppressive therapy, an adequate response may not be achieved.

Pregnancy and Lactation

Pregnancy

As Infanrix hexa is not intended for use in adults, information on the safety of the vaccine when used during pregnancy is not available.

Lactation

As Infanrix hexa is not intended for use in adults, information on the safety of the vaccine when used during lactation is not available.

Ability to perform tasks that require judgement, motor or cognitive skills

Not relevant.

Adverse Reactions

Clinical Trial Data

The safety profile presented below is based on data from more than 16,000 subjects.

As has been observed for DTPa and DTPa-containing combinations, an increase in local reactogenicity and fever was reported after booster vaccination with Infanrix hexa with respect to the primary course.

Adverse reactions reported are listed according to the following frequency:

Very common: $\geq 1/10$
Common: $\geq 1/100$ to $< 1/10$
Uncommon: $\geq 1/1000$ to $< 1/100$
Rare: $\geq 1/10000$ to $< 1/1000$
Very rare: $< 1/10000$

Infections and infestations

Uncommon: upper respiratory tract infection

Metabolism and nutrition disorders

Very common: appetite lost

Psychiatric disorders

CONFIDENTIAL

Version Number: 010
Version Date: 21 Oct 2010

Very common: irritability, crying abnormal, restlessness
Common: nervousness

Nervous system disorders

Uncommon: somnolence
Very rare: convulsions (with or without fever)

Respiratory, thoracic and mediastinal disorders

Uncommon: cough*
Rare: bronchitis

Gastrointestinal disorders

Common: vomiting, diarrhoea

Skin and subcutaneous tissue disorders

Common: pruritus*
Rare: rash
Very rare: dermatitis, urticaria*

General disorders and administration site conditions

Very common: pain, redness, local swelling at the injection site (≤ 50 mm), fever $\geq 38^{\circ}\text{C}$, fatigue
Common: local swelling at the injection site (> 50 mm)** , fever $>39.5^{\circ}\text{C}$, injection site reactions, including induration
Uncommon: diffuse swelling of the injected limb, sometimes involving the adjacent joint**

Post Marketing Data

Blood and lymphatic system disorders

Lymphadenopathy, thrombocytopenia

Immune system disorders

Allergic reactions (including anaphylactic and anaphylactoid reactions)

Nervous system disorders

Collapse or shock-like state (hypotonic-hyporesponsiveness episode)

Respiratory, thoracic and mediastinal disorders

Apnoea* [see Warnings and Precautions for apnoea in very premature infants (≤ 28 weeks of gestation)]

Skin and subcutaneous tissue disorders

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

Angioneurotic oedema*

General disorders and administration site conditions

Extensive swelling reactions, swelling of the entire injected limb**, vesicles at the injection site

* observed with other GSK DTPa-containing vaccines

** Children primed with acellular pertussis vaccines are more likely to experience swelling reactions after booster administration in comparison with children primed with whole cell vaccines. These reactions resolve over an average of 4 days.

Experience with hepatitis B vaccine:

Meningitis, mimicking serum sickness, paralysis, encephalitis, encephalopathy, neuropathy, neuritis, hypotension, vasculitis, lichen planus, erythema multiforme, arthritis, muscular weakness have been reported during post-marketing surveillance following GlaxoSmithKline Biologicals' hepatitis B vaccine in infants < 2 years old. The causal relationship to the vaccine has not been established.

Overdosage

Insufficient data are available.

As the immune response to pertussis antigens following Infanrix hexa administration is equivalent to that of Infanrix, the protective efficacy of the two vaccines is expected to be equivalent.

The protective efficacy of the pertussis component of Infanrix against WHO-defined typical pertussis (≥ 21 days of paroxysmal cough) was demonstrated in:

- a prospective blinded household contact study performed in Germany (3, 4, 5 months schedule). Based on data collected from secondary contacts in households where there was an index case with typical pertussis, the protective efficacy of the vaccine was 88.7%.
- a NIH sponsored efficacy study performed in Italy (2, 4, 6 months schedule). The vaccine efficacy was found to be 84%. In a follow-up of the same cohort, the efficacy

CONFIDENTIAL

CONFIDENTIAL

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

was confirmed up to 60 months after completion of primary vaccination without administration of a booster dose of pertussis.

Results of long term follow-up in Sweden demonstrate that acellular pertussis vaccines are highly efficacious in infants when administered according to the 3 and 5 months primary vaccination schedule, with a booster dose administered at approximately 12 months. However, data indicate that protection against pertussis may be waning at 7-8 years of age. This suggests that a second booster dose of pertussis vaccine is warranted in children aged 5-7 years who have previously been vaccinated following this schedule.

Protective immunity against hepatitis B has been shown to persist for at least 3.5 years in more than 90% of children administered four doses of Infanrix hexa. Antibody levels were not different from what was observed in a parallel cohort administered monovalent hepatitis B vaccine.

The effectiveness of the Hib component of Infanrix hexa was investigated via an extensive post-marketing surveillance study conducted in Germany. Over a seven year follow-up period, the effectiveness of the Hib components of two hexavalent vaccines, of which one was Infanrix hexa, was 89.6% for a full primary series and 100% for a full primary series plus booster dose (irrespective of the Hib vaccine used for priming).

Pharmacokinetics

Evaluation of pharmacokinetic properties is not required for vaccines.

Clinical Studies

See *Pharmacodynamic Effects*.

NON-CLINICAL INFORMATION

Preclinical data reveal no special hazard for humans based on conventional studies of safety, specific toxicity, repeated dose toxicity and compatibility of ingredients.

PHARMACEUTICAL INFORMATION

Shelf-Life

The expiry date of the vaccine is indicated on the label and packaging. The expiry date refers to the last day of the month mentioned.

The shelf-life is 3 years.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

Storage

Infanrix hexa should be stored at +2°C to +8°C. Protect from light.

During transport, recommended conditions of storage must be respected.

The DTPa-HBV-IPV suspension and the reconstituted vaccine must not be frozen.

Discard if it has been frozen.

Nature and Contents of Container

The DTPa-HBV-IPV component is presented in a pre-filled syringe or vial.

The Hib component is presented as a white pellet in a glass vial.

The vials and pre-filled syringes are made of neutral glass type I, which conforms to European Pharmacopoeia Requirements.

Vial and pre-filled syringe presentations (with or without needles) are available in packs of 1, 10, 20 and 50.

Vial and vial presentation is available in pack sizes of 1 and 50.

Incompatibilities

Infanrix hexa should not be mixed with other vaccines in the same syringe.

Use and Handling

1. Wording for vial and pre-filled syringe presentation

The DTPa-HBV-IPV suspension should be well shaken in order to obtain a homogeneous turbid white suspension. The DTPa-HBV-IPV suspension and the Hib powder should be inspected visually for any foreign particulate matter and/or variation of physical aspect. In the event of either being observed, discard the vaccine.

Infanrix hexa must be reconstituted by adding the entire content of the pre-filled syringe to the vial containing the Hib powder.

It is good clinical practice to only inject a vaccine when it has reached room temperature. In addition, a vial at room temperature ensures sufficient elasticity of the rubber closure to minimise any coring of rubber particles. To achieve this, the vial should be kept at room temperature (25 ± 3 °C) for at least five minutes before connecting the pre-filled syringe and reconstituting the vaccine.

The reconstituted vaccine presents as a slightly more cloudy suspension than the liquid component alone. This is normal and does not impair the performance of the vaccine. In the event of other variation being observed, discard the vaccine.

After reconstitution, the vaccine should be injected immediately. However the vaccine may be kept for up to 8 hours at room temperature (21°C).

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

Withdraw the entire contents of the vial.

- *Specific instructions for the pre-filled syringe with a luer lock adaptor (PRTC)*

Needle

Syringe

1. Holding the syringe **barrel** in one hand (avoid holding the syringe plunger), unscrew the syringe cap by twisting it anticlockwise.
2. To attach the needle to the syringe, twist the needle clockwise into the syringe until you feel it lock (see picture).
3. Remove the needle protector, which on occasion can be a little stiff.
4. Administer the vaccine.

2. Wording for vial and vial presentation

Upon storage, a white deposit and clear supernatant may be observed in the vial containing the DTPa-HBV-IPV suspension. This does not constitute a sign of deterioration.

Infanrix hexa must be reconstituted by adding the entire content of the vial containing the DTPa-HBV-IPV suspension to the vial containing the Hib powder. To do so, draw up the suspension with a syringe and add the suspension to the powder. The mixture should be well shaken until the powder is completely dissolved in the suspension.

The reconstituted vaccine presents as a slightly more cloudy suspension than the liquid component alone. This is normal and does not impair the performance of the vaccine.

The reconstituted vaccine should be inspected visually for any foreign particulate matter and/or abnormal physical appearance. In the event of either being observed, discard the vaccine.

A new needle should be used to administer the vaccine.

GLOBAL PATIENT LEAFLET

Title

Infanrix hexa, powder and suspension for suspension for injection

Diphtheria (D), tetanus (T), pertussis (acellular, component) (Pa), hepatitis B (rDNA) (HBV), poliomyelitis (inactivated) (IPV) and *Haemophilus influenzae* type b vaccine (adsorbed)

Read all of this leaflet carefully before your child receives this vaccine.

- Keep this leaflet. You may need to read it again.
- If you have any further questions, ask your doctor or pharmacist.
- This vaccine has been prescribed for your child. Do not pass it on to others.
- If any of the side effects gets serious, or if you notice any side effects not listed in this leaflet, tell your doctor or pharmacist.

In this leaflet

- 1. What Infanrix hexa is and what it is used for**
- 2. Before your child receives Infanrix hexa**
- 3. How Infanrix hexa is given**
- 4. Possible side effects**
- 5. How to store Infanrix hexa**
- 6. Further information**

1. What Infanrix hexa is and what it is used for

Infanrix hexa is a vaccine used to protect your child against six diseases:

- **Diphtheria:** a serious bacterial infection that mainly affects the airways and sometimes the skin. The airways become swollen causing serious breathing problems and sometimes suffocation. The bacteria also release a poison. This can cause nerve damage, heart problems, and even death.
- **Tetanus (Lockjaw):** tetanus bacteria enter the body through cuts, scratches or wounds in the skin. Wounds that are more likely to get tetanus infection are burns, fractures, deep wounds or wounds that have soil, dust, horse manure or wood splinters in them. The bacteria release a poison. This can cause muscle stiffness, painful

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

muscle spasms, fits and even death. The muscle spasms can be strong enough to cause bone fractures of the spine.

- **Pertussis (Whooping cough):** a highly infectious illness that affects the airways. It causes severe coughing that may lead to problems with breathing. The coughing often has a “whooping” sound. The cough may last for one to two months or longer. Whooping cough can also cause ear infections, chest infections (bronchitis) which may last a long time, lung infections (pneumonia), fits, brain damage and even death.
- **Hepatitis B:** is caused by the hepatitis B virus and damages the liver. The virus is found in body fluids such as in the vagina, blood, semen or spit (saliva) of infected people.
- **Poliomyelitis (Polio):** a viral infection. Polio is often only a mild illness. However, sometimes it can be very serious and cause permanent damage or even death. Polio can make the muscles unable to move (paralysis). This includes the muscles needed for breathing and walking. The arms or legs affected by the disease may be painfully twisted (deformed).
- ***Haemophilus influenzae* type b (Hib):** can cause brain swelling (inflammation). This can lead to serious problems such as mental slowness (retardation), cerebral palsy, deafness, epilepsy or partial blindness. It can also cause swelling of the throat. This can cause death by suffocation. Less commonly, the bacteria can also infect the blood, heart, lungs, bones, joints, and tissues of the eyes and mouth.

How the vaccine works

- Infanrix hexa helps your child’s body make its own protection (antibodies). This will protect your child against these diseases.
- As with all vaccines, Infanrix hexa may not fully protect all children who are vaccinated.
- The vaccine cannot cause the diseases that it protects against.

2. Before your child receives Infanrix hexa

Infanrix hexa should not be given:

- if your child is allergic (hypersensitive) to Infanrix hexa or any ingredients contained in Infanrix hexa. The active substances and other ingredients in Infanrix hexa are listed in section 6 of the leaflet. Signs of an allergic reaction may include itchy skin rash, shortness of breath and swelling of the face or tongue.
- if your child has previously had an allergic reaction to any vaccine against diphtheria, tetanus, pertussis (whooping cough), hepatitis B, poliomyelitis (polio) or *Haemophilus influenzae* type b diseases.
- if your child experienced problems of the nervous system within 7 days after previous vaccination with a vaccine against pertussis (whooping cough) disease.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

Check with your doctor if you think any of these apply to your child.

Take special care with Infanrix hexa:

- if your child has a severe infection with a high temperature. In these cases, the vaccination will be postponed until recovery. A minor infection such as a cold should not be a problem, but talk to your doctor first.
- if after previously having Infanrix hexa or another vaccine against pertussis (whooping cough) disease, your child had any problems, especially:
 - A high temperature (over 40°C) within 48 hours of vaccination
 - A collapse or shock-like state within 48 hours of vaccination
 - Persistent crying lasting 3 hours or more within 48 hours of vaccination
 - Seizures/fits with or without a high temperature within 3 days of vaccination
- if your child is suffering from neurological disorders, including infantile spasms, uncontrolled epilepsy or progressive encephalopathy (a disease of the brain)
- if your child has a bleeding problem or bruises easily
- if your child has a tendency to seizures/fits due to a fever, or if there is a history in the family of this
- if your child has breathing difficulties, please contact your doctor. This may be more common in the first three days following vaccination if your child was born prematurely (before or at 28 weeks of pregnancy).
- Children with a weakened immune system, for example due to HIV infection or due to medicines that suppress the immune system, may not get the full benefit from Infanrix hexa.
- Fainting can occur following, or even before, any needle injection, therefore tell the doctor or nurse if your child fainted with a previous injection.

Using other medicines or vaccines

Tell your doctor if your child is taking or has recently taken any other medicines, including medicines obtained without a prescription or has recently received any other vaccine.

Important information about some of the ingredients of Infanrix hexa

This vaccine contains neomycin and polymyxin (antibiotics). Tell your doctor if your child has had an allergic reaction to these ingredients.

3. How Infanrix hexa is given

- The doctor or nurse will give the recommended dose of Infanrix hexa to your child.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

- Usually, your child will receive a total of three or two injections with an interval of at least one month between each one. Each injection is given on a separate visit.
- Infanrix hexa is given as an injection of 0.5 ml into a muscle.
- You will be informed when your child should come back for the next injection.
- If additional injections (“boosters”) are necessary, the doctor or nurse will tell you.

If your child misses a dose of Infanrix hexa

If your child misses a scheduled injection, it is important that you make another appointment.

Make sure your child finishes the complete vaccination course. If not, your child may not be fully protected against the diseases.

4. Possible side effects

Like all medicines, Infanrix hexa can cause side effects, although not everybody gets them.

The following side effects may happen with this vaccine:

Allergic reactions

As with all injectable vaccines, severe allergic reactions (anaphylactic and anaphylactoid reactions) may very rarely occur (up to 1 in 10,000 doses of vaccine). These can be recognised by:

- itchy rash of the hands and feet
- swelling of the eyes and face
- difficulty in breathing or swallowing
- sudden drop in blood pressure and loss of consciousness

These reactions will usually occur before leaving the doctor’s surgery. However, if your child gets any of these symptoms you should contact a doctor urgently.

See your doctor straight away if your child has any of the following serious side effects:

- collapse
- times when they lose consciousness or have a lack of awareness
- fits – this may be when they have a fever

These side effects have happened very rarely with other vaccines against whooping cough. They usually happen within 2 to 3 days after vaccination.

Other side effects include:

CONFIDENTIAL

CONFIDENTIAL

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

Very common (these may occur with more than 1 in 10 doses of the vaccine):

- loss of appetite
- unusual crying
- feeling irritable or restless
- pain, redness and swelling where the injection was given
- fever of 38°C or higher
- feeling tired

Common (these may occur with up to 1 in 10 doses of the vaccine):

- feeling nervous
- being sick (vomiting)
- diarrhoea
- fever higher than 39.5°C
- swelling larger than 5 cm where the injection was given
- hard lump where the injection was given
- itching

Uncommon (these may occur with up to 1 in 100 doses of the vaccine):

- upper respiratory tract infection
- feeling sleepy
- cough
- large swelling of the vaccinated limb

Rare (these may occur with up to 1 in 1,000 doses of the vaccine):

- bronchitis
- rash

Very Rare (these may occur with up to 1 in 10,000 doses of the vaccine):

- swollen glands in the neck, armpit or groin (*lymphadenopathy*)
- Bleeding or bruising more easily than normal (*thrombocytopenia*)
- temporarily stopping breathing (*apnoea*)
- in babies born very prematurely (at or before 28 weeks of gestation) longer gaps than normal between breaths may occur for 2-3 days after vaccination
- swelling of the face, lips, mouth, tongue or throat which may cause difficulty in swallowing or breathing (*angioneurotic oedema*)
- swelling of the whole injected limb
- blister where the injection was given
- hives (*urticaria*)
- skin rash (*dermatitis*)

If your child gets side effects

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
 Version Number: 010
 Version Date: 21 Oct 2010

If any of the side effects gets serious, or if you notice any side effects not listed in this leaflet, tell your doctor or pharmacist.

5. How to store Infanrix hexa

- Store in a refrigerator (2°C – 8°C).
- Store in the original package in order to protect from light.
- Do not freeze. Freezing destroys the vaccine.
- Keep out of the reach and sight of children.
- Do not use Infanrix hexa after the expiry date which is stated on the carton. The expiry date refers to the last day of that month.
- Medicines should not be disposed of via wastewater or household waste. Ask your pharmacist how to dispose of medicines no longer required. These measures will help to protect the environment.

6. Further information

What Infanrix hexa contains

1 dose (0.5 ml) contains:

The active substances are:

Diphtheria toxoid ¹	not less than 30 International Units
Tetanus toxoid ¹	not less than 40 International Units
<i>Bordetella pertussis</i> antigens	
Pertussis toxoid ¹	25 micrograms
Filamentous Haemagglutinin ¹	25 micrograms
Pertactin ¹	8 micrograms
Hepatitis B surface antigen ^{2,3}	10 micrograms
Poliovirus (inactivated)	
type 1 (Mahoney strain) ⁴	40 D-antigen unit
type 2 (MEF-1 strain) ⁴	8 D-antigen unit
type 3 (Saukett strain) ⁴	32 D-antigen unit
<i>Haemophilus influenzae</i> type b polysaccharide (polyribosylribitol phosphate) ³	10 micrograms
conjugated to tetanus toxoid as carrier protein	20-40 micrograms

¹adsorbed on aluminium hydroxide, hydrated (Al(OH)₃) 0.5 milligrams Al³⁺

²produced in yeast cells (*Saccharomyces cerevisiae*) by recombinant DNA technology

³adsorbed on aluminium phosphate (AlPO₄) 0.32 milligrams Al³⁺

⁴propagated in VERO cells

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

The other ingredients in Infanrix hexa are:

Hib powder: lactose

DTPa-HBV-IPV suspension: sodium chloride (NaCl), Medium 199 (as stabilizer including amino acids, mineral salt and vitamins) and water for injections.

Potassium chloride, disodium phosphate, monopotassium phosphate, polysorbate 20 and 80, glycine, formaldehyde, neomycin sulphate and polymyxin B sulphate are present as residues.

What Infanrix hexa looks like and contents of the pack

The diphtheria, tetanus, acellular pertussis, hepatitis B, inactivated poliomyelitis (DTPa-HBV-IPV) component is a turbid white suspension presented in a pre-filled syringe (0.5 ml) or vial (0.5 ml).

The Hib component is a white powder presented in a vial.

Infanrix hexa is available in packs of 1, 10, 20 and 50 with or without needles (pre-filled syringe and vial presentation) or in packs of 1 and 50 (vial and vial presentation).

Not all pack sizes may be marketed.

Instructions for use

The following information is intended for medical or healthcare professionals only:

- Administration of the vial and pre-filled syringe presentation

The DTPa-HBV-IPV suspension should be well shaken in order to obtain a homogeneous turbid white suspension. The DTPa-HBV-IPV suspension and the Hib powder should be inspected visually for any foreign particulate matter and/or variation of physical aspect. In the event of either being observed, discard the vaccine.

Infanrix hexa must be reconstituted by adding the entire content of the pre-filled syringe to the vial containing the Hib powder.

It is good clinical practice to only inject a vaccine when it has reached room temperature. In addition, a vial at room temperature ensures sufficient elasticity of the rubber closure to minimise any coring of rubber particles. To achieve this, the vial should be kept at room temperature (25 ± 3 °C) for at least five minutes before connecting the pre-filled syringe and reconstituting the vaccine.

The reconstituted vaccine presents as a slightly more cloudy suspension than the liquid component alone. This is normal and does not impair the performance of the vaccine. In the event of other variation being observed, discard the vaccine.

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated) and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

After reconstitution, the vaccine should be injected immediately. However the vaccine may be kept for up to 8 hours at room temperature (21°C).

Withdraw the entire contents of the vial.

- *Specific instructions for the pre-filled syringe with a luer lock adaptor (PRTC)*

Needle

Syringe

1. Holding the syringe **barrel** in one hand (avoid holding the syringe plunger), unscrew the syringe cap by twisting it anticlockwise.
2. To attach the needle to the syringe, twist the needle clockwise into the syringe until you feel it lock (see picture).
3. Remove the needle protector, which on occasion can be a little stiff.
4. Administer the vaccine.

Any unused product or waste material should be disposed of in accordance with local requirements.

- Administration of the vial and vial presentation

Upon storage, a white deposit and clear supernatant may be observed in the vial containing the DTPa-HBV-IPV suspension. This does not constitute a sign of deterioration.

Infanrix hexa must be reconstituted by adding the entire content of the vial containing the DTPa-HBV-IPV suspension to vial containing the Hib powder. To do so, draw up the suspension with a syringe and add the suspension to the powder. The mixture should be well shaken until the powder is completely dissolved in the solvent.

CONFIDENTIAL

CONFIDENTIAL

Active Name: Combined diphtheria, tetanus, pertussis (acellular), hepatitis B, poliomyelitis (inactivated)
and *Haemophilus influenzae* type b vaccine
Version Number: 010
Version Date: 21 Oct 2010

The reconstituted vaccine presents as a slightly more cloudy suspension than the liquid component alone. This is normal and does not impair the performance of the vaccine.

The reconstituted vaccine should be inspected visually for any foreign particulate matter and/or abnormal physical appearance. In the event of either being observed, discard the vaccine.

A new needle should be used to administer the vaccine.

After reconstitution, the vaccine should be used immediately.

Withdraw the entire contents of the vial.

Any unused product or waste material should be disposed of in accordance with local requirements.

Appendix 4A: Summary Tabulation of Adverse Events Included in the Line Listing for:

Infanrix hexa

N.B. Events are only considered serious if they fulfil GSK medically serious criteria. GSK medically serious criteria are applied automatically only to events from spontaneous, post-marketing or literature case reports. Events arising from Clinical trial cases are not run against the list of GSK medically serious terms. For this reason events may appear as both serious and non-serious. For full explanation see section 6.2.2.

MedDRA SOC	HLGT	Event (PT)	Listed	Serious	Non-serious	Total Cases for current period

**Appendix 4C: Summary Tabulation of Adverse Events from Non-Medically
Verified, Serious Listed + Unlisted + Non-Serious Unlisted Cases for:**

Infanrix hexa

N.B. Events are only considered serious if they fulfil GSK medically serious criteria. GSK medically serious criteria are applied automatically only to events from spontaneous, post-marketing or literature case reports. Events arising from Clinical trial cases are not run against the list of GSK medically serious terms. For this reason events may appear as both serious and non-serious. For full explanation see section 6.2.2.

7. & 13. DESCRIBE EVENT(S) Metabolic disorder, Ataxia, Balance disorder, Diplopia, Strabismus, Nervous system disorder, This case was reported by a physician via a GSK employee and described the occurrence of ataxia in a 6-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline), pneumococcal vaccines (non-GSK) (Prevenar) for prophylaxis. The subject's medical history included episodes of shaking of head and arms and legs several times a day. These episodes occurred previous the 5-month vaccinations and lasted a few days. On an unspecified date, the subject received 3rd dose of Infanrix hexa (intramuscular, unknown injection site), 3rd dose of Prevenar (intramuscular, unknown injection site) according to the national immunization schedule. <p>7. & 13. DESCRIBE EVENT(S)</p> <p>5 days after vaccination with Infanrix hexa and Prevenar, the subject experienced ataxia, instability and diplopia. The physician suspected a possible neurological alteration.</p> <p>The subject was hospitalized and some relevant tests were performed and showed normal results.</p> <p>Two or three days later, the symptoms resolved but the baby still had some instability. One week later, the subject experienced another episode of ataxia and diplopia, and one month later again. When the episodes occurred, the baby was always awake.</p> <p>All the examinations made were normal: NMR, ECG, CSF, Laboratory tests, nasopharyngeal exudates. The only test pending was the catecholamine.</p> <p>At the time of reporting, the events were unresolved, the ataxia was still present but in lower intensity.</p> <p>According to the reporter opinion, the events were unlikely to be related to the vaccinations, but the relationship could not be ruled out by the moment.</p> <p>Follow up information received on 30 June 2010:</p> <p>When the patient was 5 months old he presented paroxistic episodes with head shaking (NMR performed was normal). When he was 6 months old, about 5 days after vaccination with Infanrix Hexa and Prevenar, he had an episode of diplopia (described as strabismus) and ataxia. The ataxia remained until the age of 9 months. The shaking moves have repeated in some occasions. Metabolic status was normal. Since the patient started with neurological profile a month before, it seemed possible that he could have a previous problem more than a vaccine reaction.</p> <p>The reporter assessed this case as clinically significant. He reported that the patient was hospitalized at the time of reporting but it is not confirmed.</p> <p>Further information is expected.</p> <p>Follow up information received on 9 July 2010:</p> <p>Previous vaccination included combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (GlaxoSmithKline); meningococcal b c vaccine (non-GSK manufacturer); pneumococcal vaccines (non-GSK manufacturer) given on an unspecified date at the age of 2 months and 4 months.</p> <p>On 25 March 2010, 5 days after vaccination with Infanrix hexa and Prevenar, the subject experienced certain trunk instability when sitting, although he could maintain the position without support. No shivering on limbs was noted.</p> <p>Relevant test results included: EEG normal, previous magnetic resonance normal. Catecholamines and muscular biopsy results were still pending.</p> <p>The subject underwent EEG in July 2010 and showed 3 lesions compatibles with metabolic disorder.</p> <p>The final diagnosis was a possible metabolic disease.</p> <p>He was hospitalized in the pediatric intensive care due to a possible aspiration from 16 to 24 June 2010.</p> <p>At the time of reporting, the subject was stable at home with very few clinic.</p> <p>Follow up information received on 19 August 2010:</p> <p>The subject died in July 2010 due to a possible metabolic disorder of a mitochondrial origin. The events seemed to be unrelated to vaccination.</p> <table border="1"> <thead> <tr> <th>LABORATORY TEST NAME</th> <th>TEST DATE</th> <th>TEST RESULT</th> <th>LOW NORMAL</th> <th>HIGH NORMAL</th> </tr> </thead> <tbody> <tr> <td> </td> <td> </td> <td> </td> <td> </td> <td> </td> </tr> </tbody> </table>			LABORATORY TEST NAME	TEST DATE	TEST RESULT	LOW NORMAL	HIGH NORMAL

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>Prevenar, on 02 October 2009, the subject died from an unknown cause. An autopsy was performed. An autopsy report was not provided.</p> <p>Post-mortem showed uncharacteristic findings, nevertheless according to the emergency physician the subject showed high fever of 39.4 degC.</p> <p>The subject experienced no consecutive symptoms in the time between date of vaccination with Infanrix hexa and Prevenar and date of death from an unknown cause. Therefore the reporter considered that death from an unknown cause occurred coincidentally and most likely only by chance to vaccination with Infanrix hexa.</p> <p>Follow-up information was received on 18 December 2009 from the German regulatory authority (DE-Paul-Ehrlich-Institut).</p> <p>The subject's parents have separated about two weeks prior to the events. The subject was cared for by the father with help of sister in law and mother in law.</p> <p>On 29 September 2009 the subject received the first dose of Infanrix hexa (0.5 ml, intramuscular, left thigh) and the first dose of Prevenar (0.5 ml, intramuscular, right thigh), contralaterally.</p> <p>Approximately three days post vaccination with Infanrix hexa and Prevenar, on 02 October 2009, the subject experienced cardiovascular arrest.</p> <p>The subject was hospitalised for cardiopulmonary resuscitation. The events were reported to be life threatening.</p> <p>In the morning of 02 October 2009 at around 07:30 the subject appeared normal. About half an hour later, on 02 October 2009 at around 08:00, the subject was supposed to be fed with a bottle. The subject was found unconscious and the subject's body got blue (cyanosis). Upon arrival of an emergency physician the pupils were medium wide, no pulse could be determined and oxygen saturation could not be measured. The subject was intubated and cardiopulmonary resuscitation was started. Under ongoing resuscitation the subject was transferred to a hospital. In hospital the subject was treated with adrenaline (Suprarenin) and atropine (Atropin), which were intraosseously administered. Nevertheless the pupils showed no reaction to light. Transthoracic echocardiography and electrocardiogram (ECG) both showed no detectable heart reaction. Body temperature, taken in the ear, was 39.4 degC. Resuscitation was without success and was stopped on 02 October 2009 at 09:14. Natural cause of death was not unambiguously clear. Therefore the police was informed for further investigations.</p> <p>The subject died on 02 October 2009 from cardiovascular arrest. By differential diagnosis possible sudden infant death syndrome (SIDS) or possible fulminant sepsis were considered.</p> <p>An autopsy was performed. The results of autopsy were not conclusive. According to autopsy both sudden infant death syndrome (SIDS) and viral infection were possible causes of death. External force and shaken impact syndrome (shaken baby syndrome) were excluded by autopsy.</p> <p>No further information will be available.</p> <table border="0"> <tr> <td>LABORATORY TEST NAME</td> <td>TEST DATE</td> <td>TEST RESULT</td> <td>LOW NORMAL</td> <td>HIGH NORMAL</td> </tr> <tr> <td>Body temperature</td> <td>02Oct2009</td> <td>39.4degC</td> <td></td> <td></td> </tr> </table>			LABORATORY TEST NAME	TEST DATE	TEST RESULT	LOW NORMAL	HIGH NORMAL	Body temperature	02Oct2009	39.4degC

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>of Infanrix hexa (0.5 ml, unknown, unknown thigh).</p> <p>Approximately nine days post vaccination with Synflorix and Infanrix hexa, on 13 November 2009, the subject died from sudden infant death syndrome (SIDS). The event was also reported as life threatening.</p> <p>It was not specified whether an autopsy was performed.</p> <p>One vaccine was reported as a lot number only, but was identified as 10 valent pneumococcal conjugate vaccine (Synflorix, GlaxoSmithKline) according to lot number. The other vaccine was reported as diphtheria and tetanus toxoids and acellular pertussis vaccine (Infanrix, GlaxoSmithKline), but according to lot number the subject was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline).</p> <p>On 21 January 2010 the German regulatory authority (DE-Paul-Ehrlich-Institut) informed that despite of repeated requests no further information could be obtained up to now.</p> <p>Follow-up information including autopsy report was received on 05 March 2010 from the German regulatory authority (DE-Paul-Ehrlich-Institut).</p> <p>The subject was found lifeless on 13 November 2009 at 11:40 in bed in supine position covered by a cushion / pillow. An emergency physician was only able to certify death. The subject has had no underlying medical conditions. According to a police report the children's room was severely overheated and in the whole apartment people had been smoking (passive smoking).</p> <p>Autopsy was performed on 20 November 2009 and showed age-corresponding state of development and very good state of care. Both height and weight was 50 percentile. Multiple punctual haemorrhages up to the size of a pinhead were found under the thymus capsule, subepicardial and on the surface of the lungs. Distinct disorder of blood distribution was seen in the lungs as well as increased fluid and blood content in the lungs and foam in the respiratory tract (pulmonary edema). Neither signs of external force by a third party nor signs of shaken baby syndrome have been detected. No signs of organic malformation have been detected.</p> <p>The cause of death could not be unambiguously determined. Punctual haemorrhages under the thymus capsule, subepicardial and on the surface of the lungs were normally seen within the scope of sudden infant death syndrome (SIDS) and therefore the autopsy performing physicians considered SIDS. Possible risk factors associated with SIDS included coverage with a pillow, severely overheating of the surrounding, not feeding with breast milk and nicotine abuse of the parents. Furthermore autopsy showed increased water retention of the lungs as well as distinct disorder of blood distribution within the lungs. These findings could be signs of a beginning pulmonary infection. Therefore histological and microbiological examinations will be performed. Additionally chemical toxicological examinations will be performed to exclude intoxication. Shaken baby syndrome has been excluded by preparation of the bridging veins.</p> <p>Microbiological examinations, performed on 20 November 2009, showed solitary Staphylococcus aureus in both pulmonary swabs and a single Staphylococcus aureus colony in the spleen swab as potential infectious agent, but this bacterium was also known as normal bacterial flora of the upper respiratory tract. All other bacteria found belong either to physiological intestinal flora or were normal parts of the throat and skin flora.</p> <p>Microscopically no signs of inflammation could be detected. Therefore infectious events could be excluded with some probability. Final conclusions could from microscopic examinations can only been made including histopathologic results.</p> <p>No further information will be available.</p> <table style="width:100%; border: none;"> <tr> <td style="width:40%;">LABORATORY TEST NAME</td> <td style="width:15%;">TEST DATE</td> <td style="width:20%;">TEST RESULT</td> <td style="width:15%;">LOW NORMAL</td> <td style="width:10%;">HIGH NORMAL</td> </tr> <tr> <td>Head circumference</td> <td></td> <td>38cm</td> <td></td> <td></td> </tr> <tr> <td>MEDICAL CONDITION</td> <td>START DATE</td> <td>END DATE</td> <td colspan="2">CONTINUING</td> </tr> <tr> <td>PASSIVE SMOKING</td> <td>Unknown</td> <td>Unknown</td> <td colspan="2">Yes</td> </tr> </table>			LABORATORY TEST NAME	TEST DATE	TEST RESULT	LOW NORMAL	HIGH NORMAL	Head circumference		38cm			MEDICAL CONDITION	START DATE	END DATE	CONTINUING		PASSIVE SMOKING	Unknown	Unknown	Yes

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>It was unknown whether an autopsy was performed.</p> <p>Follow-up information was received on 21 December 2009 from the reporting physician. Additional information was received by fax on the same day from the reporting physician.</p> <p>On 09 December 2009 the subject received the first dose of Infanrix hexa (0.5 ml, intramuscular, right deltoid) and the first dose of Prevenar (0.5 ml, intramuscular, left deltoid), contralaterally.</p> <p>Approximately one day post vaccination with Infanrix hexa and Prevenar, on 10 December 2009, the subject died from sudden infant death syndrome (SIDS). It was unknown whether an autopsy was performed.</p> <p>The reporting physician also provided the answers to a GSK questionnaire asking for additional information in cases of sudden infant death syndrome (SIDS):</p> <p>The mother was married. No information was provided concerning employment of father and mother, age of father and mother and the number of brothers and sisters.</p> <p>None of the following diseases were known in family history: metabolic disorders or inborn errors of metabolism, cardiac problems, non-accidental injury in child and non-accidental injury in siblings. It was unknown, whether or not family history included, SIDS or SUD, near miss, infant death due to other reason or epilepsy or convulsions. It was unknown whether or not either mother or father was smoking. No information was provided whether or not mother or father were abusing alcohol and drugs. The subject's family was living in a rural region.</p> <p>The mother had been pregnant for an unknown number of times with 2 deliveries. It was unknown whether or not conditions during present pregnancy included maternal illness or complication during pregnancy, maternal smoking or maternal medication. It was unknown whether or not the mother took any medication during breast feeding. It was unknown whether or not there was any fetal distress.</p> <p>The subject was born by normal delivery at 39 weeks with a birth weight of 2800 g, unspecified length, unspecified head circumference and unspecified APGAR score. There were no birth defects. The subject was breast-fed for three months. The subject's development and weight gain were normal.</p> <p>The subject had none of the following pre-existing diseases: allergies, inborn errors of metabolism or enzymatic abnormalities, episodes of cyanosis, stop breathing or apnea, gastroesophageal reflux, convulsions, sleep disorder, past surgery or known mistreatment. The subject had none of the following conditions in the past two weeks: emergency room visit, exposure to contagious disease, infection, fever, excessive sweating during sleep, loud breathing or snoring during sleep, vomiting, appetite changes, diarrhea or stool changes, dyspnea, abnormal crying or lethargy. There were no recent changes of the way of life..</p> <p>The subject had received the last meal, consisting of mother's breast milk on 10 December 2009. Afterwards the subject was brought to bed. About one hour later when looking for the subject everything was normal. About two hour later the subject was found dead in bed in supine position.</p> <p>On an unspecified time on 10 December 2009 the subject was found dead in the bed. The subject was found by chance. It was unknown whether the subject was sleeping alone. The subject was sleeping in the bed. When placed, the position of body was face up. When found, the position of body was face up. Sleeping or supporting surface, items in contact with infant or in immediate environment included, the number of blankets covering the subject, body temperature of the subject at the time when found dead and room temperature at the time when found dead were unknown. The subject was looked after by the mother.</p> <p>The subject has received no previous vaccinations.</p> <p>Follow-up information of the same case was received on 04 January 2010 from the German regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2009030789).</p>

<p>Co-suspect vaccinations included 7 valent pneumococcal conjugate vaccine (non-GSK) (Prevenar, Wyeth).</p> <p>The subject was a healthy infant and received breast feeding. No concomitant medication has been reported.</p> <p>On 09 December 2009 at approximately 09:45 the subject received the first dose of Infanrix hexa (0.5 ml, intramuscular, unknown) and the first dose of Prevenar (0.5 ml, intramuscular, unknown).</p> <p>Post vaccination with Infanrix hexa and Prevenar the subject experienced no adverse reaction like fever. On the next morning, on 10 December 2009, the subject was normally drinking and was put to bed. Approximately two to three hours later, on 10 December 2009, the subject was found lifeless in bed in supine position.</p> <p>The cause of death was reported as sudden infant death syndrome (SIDS). An autopsy was performed, but results were not provided.</p> <p>No additional information was available at the time of this report but additional information has been requested.</p> <p>On 28 January 2010 the reporting physician confirmed the reported date of birth of the subject to be 08 September 2009.</p> <p>Follow-up information was received on 04 March 2010 from the German regulatory authority (DE-Paul-Ehrlich-Institut).</p> <p>The German regulatory authority (DE-Paul-Ehrlich-Institut) informed that case D0066295A was identified to be a duplicate of case D0065445A. All future correspondence of case D0066295A will be submitted to this case. Additionally, the German regulatory authority (DE-Paul-Ehrlich-Institut) identified a third case received to be also a duplicate of this case of record (case D0065445A). The new only active PEI number for all PEI cases was now DE-PEI-PEI2009029991. The PEI cases with the numbers DE-PEI-PEI2009030789 and DE-PEI-PEI2010002277 will be nullified.</p> <p>The duplicate case D0066295A was initially received on 28 January 2010 from the German regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2010002277).</p> <p>At the time of vaccination the subject was healthy.</p> <p>Co-suspect vaccination included pneumococcal vaccine (non-GSK) (Prevenar, Wyeth).</p> <p>On 09 December 2009 at 09:30 or 09:45 the subject received an unspecified dose of Infanrix hexa (intramuscular, unknown thigh) and an unspecified dose of Prevenar (intramuscular, unknown thigh), contralaterally.</p> <p>On 09 December 2009 and in the morning of the next day, on 10 December 2009, the subject was normal and showed no adverse effect. The subject was breast fed in the morning of 10 December 2009. The subject was drinking normal. After breast feeding the subject was put to bed.</p> <p>Approximately two to three hours later, on 10 December 2009, the subject was found dead in bed in supine position. An emergency physician was called.</p> <p>The subject died on 10 December 2009 from sudden infant death syndrome (SIDS). An autopsy was performed, but no results were available at the time of reporting.</p> <p>At the moment no further information will be available.</p> <table border="0"> <tr> <td>MEDICAL CONDITION</td> <td>START DATE</td> <td>END DATE</td> <td>CONTINUING</td> </tr> <tr> <td>BREAST FEEDING</td> <td>Unknown</td> <td>Unknown</td> <td>Yes</td> </tr> </table>			MEDICAL CONDITION	START DATE	END DATE	CONTINUING	BREAST FEEDING	Unknown	Unknown	Yes

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>It was not reported whether an autopsy was performed.</p> <p>Follow-up information was received on 15 January 2010 by phone from the reporting physician.</p> <p>The subject has three healthy siblings. The subject was healthy. The subject was breast fed. The subject's mother did not smoke.</p> <p>On 29 December 2009 the fourth preventive medical examination for infants (U4) was performed.</p> <p>On 29 December 2009 at around 10:00 the subject received the first dose of Infanrix hexa (0.5 ml, unknown) and the first dose of Prevenar (0.5 ml, unknown) at the reporting physician's practice.</p> <p>According to the subject's mother, after leaving the practice on the way home, the subject has fallen asleep and did not wake up again. It was not quite clear at which time the subject was found dead. The subject must have died in the evening of 29 December 2009 or in the night between 29 December 2009 and 30 December 2009.</p> <p>An autopsy was performed on an unknown date. According to verbal information to the reporter autopsy showed no pathologic findings. Sudden infant death syndrome (SIDS) was considered. According to verbal information to the reporter no causal relationship of possible sudden infant death syndrome (SIDS) to vaccination with Infanrix hexa and Prevenar was considered.</p> <p>On 18 January 2010 the same case was received from a German regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2010000799).</p> <p>The subject's past medical condition was not provided.</p> <p>On 29 December 2009 the subject received a dose of Infanrix hexa (0.5 ml, intramuscular, unknown) and a dose of Prevenar (0.5 ml, intramuscular, unknown).</p> <p>In the night post day of vaccination the subject was found dead in bed.</p> <p>The German regulatory authority (DE-Paul-Ehrlich-Institut) reported date of death to be 30 December 2009 and cause of death to be possible sudden infant death syndrome (SIDS).</p> <p>The case was reported to be life threatening.</p> <p>An autopsy was performed, but the German regulatory authority (DE-Paul-Ehrlich-Institut) has not received the autopsy report up to now.</p> <p>On 21 January 2010 the German regulatory authority (DE-Paul-Ehrlich-Institut) informed that despite of repeated requests no further information could be obtained up to now.</p> <p>Follow-up information was received on 02 February 2010 from the reporting physician.</p> <p>The subject has no underlying or concurrent medical conditions or other risk factors. The subject received no concomitant medication.</p> <p>On 29 December 2009 the subject received the first dose of Infanrix hexa (0.5 ml, intramuscular, right thigh) and the first dose of Prevenar (0.5 ml, intramuscular, left thigh), contralaterally.</p> <p>Less than one day post vaccination with Infanrix hexa and Prevenar, on 29 December 2009, the subject died. The subject received no treatment. An autopsy was performed. The results of autopsy were inconclusive and showed no obvious cause of death. Therefore cause of death was considered to be sudden infant death syndrome (SIDS).</p> <p>The reporting physician also provided the answers to a GSK questionnaire asking for additional information in cases of sudden infant death syndrome (SIDS):</p> <p>The mother was married and cohabiting with her husband. The mother was not employed and the father's state of employment was unknown. The ages of the mother and the father were not reported. The subject had two brothers and one sister.</p> <p>None of the following diseases were known in family history: metabolic disorders or inborn errors of metabolism, cardiac problems, SIDS or SUD, near miss, infant death due</p>		

CONFIDENTIAL

CONFIDENTIAL

D0066068A	DESK COPY	(Page 3 of 3)
<p>to other reason, epilepsy or convulsions, non-accidental injury in child, non-accidental injury in siblings. The mother or and father did not smoke, abuse alcohol and drugs. The subject's family was living in a rural region.</p> <p>The mother had been pregnant for four times with four deliveries.</p> <p>During present pregnancy there was no maternal illness or complication, maternal smoking or maternal medication. There was no maternal medication during breast feeding. There was no fetal distress.</p> <p>The subject was born by normal delivery at unknown week of pregnancy as mature newborn with a birth weight of 3760 g, an unknown length, an unknown head circumference and an APGAR score of 10/10. There were no birth defects. The subject was breast-fed until death. The subject development well and weight gain was normal.</p> <p>The subject had none of the following pre-existing diseases: allergies, inborn errors of metabolism or enzymatic abnormalities, episodes of cyanosis, stop breathing or apnea, gastroesophageal reflux, convulsions, sleep disorder, past surgery, mistreatment prior to contact with social worker or other relevant medical conditions. The subject had none of the following conditions in the past two weeks: emergency room visit, exposure to contagious disease, infection, fever, excessive sweating during sleep, loud breathing or snoring during sleep, vomiting, appetite changes, diarrhea or stool changes, dyspnea, abnormal crying, lethargy or other relevant medical conditions. There were no recent changes of the way of life..</p> <p>The subject had received the last meal, consisting of mother's milk on 29 December 2009 in the evening</p> <p>On 29 December 2009 in the evening the subject was found dead under unknown circumstances in the bed. The subject was found by chance. It was unknown whether or not the subject was sleeping alone in the bed. When placed, the position of body was unknown. When found, the position of body was unknown. The type of sleeping or supporting surface was unknown. Whether there were items in contact with infant or in immediate environment was unknown. Whether the subject was covered by one or more blankets was unknown. Body temperature when found was unknown. Room temperature when found was unknown. The type of heating was unknown. The subject was looked after by the mother.</p> <p>There were no adverse events following the last vaccination because vaccination with Infanrix hexa and Prevenar was the first course of vaccination received ever.</p> <p>No further information will be available.</p>

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>Past medical history was not provided. It was unknown whether or not the subject has received any previous vaccinations and how these vaccinations may have been tolerated.</p> <p>On 31 March 2010 the subject received an unspecified dose of Infanrix hexa (0.5 ml, unknown) and an unspecified dose of Prevenar 13 (0.5 ml, unknown)</p> <p>Approximately three days post vaccination with Infanrix hexa and Prevenar 13, on 03 April 2010, the subject experienced sudden infant death syndrome (SIDS).</p> <p>The event was reported to be life threatening.</p> <p>The subject died on 03 April 2010 from sudden infant death syndrome (SIDS) according to diagnosis by an emergency physician.</p> <p>An autopsy was performed but autopsy revealed no obvious cause of death and therefore the cause of death could not be determined (death due to unknown cause).</p> <p>Follow-up information including protocol from the emergency physician was received in 14 June 2010 from the German regulatory authority (DE-Paul-Ehrlich-Institut).</p> <p>Concurrent medical conditions included old contusion and hematoma on right side of chest.</p> <p>On 03 April 2010 in the morning the subject experienced apnea. On 03 April 2010 at 09:42 an emergency physician was called and arrived about five minutes later on 03 April 2010 at 09:47. When the emergency care team arrived the subject was unconscious. Cardiac arrest with apnea and asystole was diagnosed. Resuscitation was unsuccessful. Sudden infant death syndrome (SIDS) was suspected. The subject was declared dead on 03 April 2010 at 10:03.</p> <p>Follow-up information, received on 17 June 2010 from the German regulatory authority (DE-Paul-Ehrlich-Institut), contained no new information.</p> <p>Follow-up information including preliminary autopsy report was received in 18 June 2010 from the German regulatory authority (DE-Paul-Ehrlich-Institut).</p> <p>Complication during pregnancy included cranial hemorrhage of the mother due to cerebral artery aneurysm in the 19th week of gestation. The subject was born in the 33rd week of pregnancy by Caesarean section. The subject's medical history was uneventful. The subject seemed to be healthy. During last scheduled prophylactic medical examination of infants, on 31 March 2010, the subject showed no conspicuous findings. On the same date the subject was vaccinated with Infanrix hexa.</p> <p>Approximately three days post vaccination with Infanrix hexa, on 03 April 2010, the subject was brought to bed by the father. About one hour later, the subject was found lifeless. The subject was in the crib in prone position. An emergency physician was called immediately. Resuscitation by the emergency physician was unsuccessful.</p> <p>Autopsy was performed on 06 April 2010 from 09:30 to 10:30.</p> <p>According to percentile curve of the WHO the subject was in reduced nutritional condition with a weight of 3700 g and a height 55cm. Autopsy showed multiple punctual, in parts confluent hemorrhage under the serous membranes of thymus gland and heart, bloated lungs (pulmonary emphysema) both sides and signs of shock kidneys both sides, tiny fissures of skin at the left corner of the mouth, extensive ecchymoses in the area of the central chest wall and the upper epigastric region, two small round ecchymoses in the line of the left mamilla, hemorrhage in the connective tissue like capsule of the right adrenal gland and right kidney. Macroscopically, autopsy revealed no unambiguous cause of death. All autopsy findings were known to occur in cases of sudden infant death syndrome (SIDS). The findings not consistent with SIDS (skin fissures in the corner of mouth, ecchymoses in area of central chest wall, hemorrhage in capsule of adrenal gland and kidney) can be explained with plausibility by long and continuous resuscitation. Final diagnosis of SIDS has not been made because SIDS is a diagnosis based on exclusion of other diagnoses and additional examinations, including histology and toxicology, have not been performed. Furthermore, death due to causes which provide little traces or medical findings, like e.g. soft covering, might stay undetected by autopsy. The cause of death was unknown. The manner of death was unsolved.</p> <p>Follow-up information concerning medical history was received in 09 July 2010 from the German regulatory authority (DE-Paul-Ehrlich-Institut).</p>

-----------	-----------	---------------

The subject's mother experienced severe cerebral hemorrhage in October 2009 in the 19th week of pregnancy. The subject's mother was cared for at a neurosurgery department followed by rehabilitation measures.

The subject was born premature in the 33 + 2 week of pregnancy by caesarean section. At that time the subject was immature with a birth weight of 1805 g /(20th percentile), length of 43 cm (25th percentile), head circumference of 32 cm, Apgar score of 8/9/9, umbilical blood ph of 7.35 and mild respiratory distress syndrome with 23 % oxygen demand. The subject was hospitalised from 27 January 2010 to 18 February 2010. Postnatal the subject showed good adaptation, but chest X-ray, performed on 28 January 2010, showed mixed picture of mild neonatal respiratory distress syndrome and wet lung. Repeated central nervous system (CNS) sonography, performed on 28 January 2010, 29 January 2010 and 08 February 2010, as well as neonatal screening, performed on 29 January 2010 and 15 February 2010, were normal. The subject developed normal without complications. On 18 February 2010 the subject was discharged from hospital in stable general condition.

Concurrent medications included colecalciferol (Vitamin D3) and iron salt (Iron).

In third child health check, performed on 04 March 2010, the subject showed normal development concerning weight, length and head circumference. The subject showed no pathologic findings except mild hydrocele.

In fourth child health check, performed on 31 March 2010, the subject showed no pathologic findings. The subject received the first dose of Infanrix hexa and the first dose of Prevenar 13.

Approximately three days later, on 03 April 2010, the subject died from possible sudden infant death syndrome (SIDS).

Follow-up information was received via the regulatory authority on 16 September 2010. Reports on toxicologic and histologic examinations, performed on 18 August 2010, were provided. Findings were summarized by the regulatory authority as follows: "Unexplained death (no definite cause of death), probably sudden infant death syndrome, according to the autopsy report as well as to the toxicologic and histologic examinations. No further information was available at the date of this report."

According to the report on the toxicologic examination, there were no findings which could identify the cause of death. Any examination had resulted negatively / normally. Urine analysis revealed detectable concentrations of paracetamol and lidocaine. Lidocaine might possibly be due to the reanimation procedures. Paracetamol might be due to a possible treatment of febrile infection during the last days prior to the subject's death. As the subject's blood was free of paracetamol, the finding was considered not contributory.

According to the report on the histologic examination, results largely confirmed the findings of the autopsy. Results included hemostasis of inner organs, cerebral edema, haemorrhage of the organs' connective tissue coatings and acute pulmonary emphysema. Besides unspecific signs of death, punctuate haemorrhage of the organs' connective tissue coatings and pulmonary emphysema were considered the essential findings. Acute emphysema could be interpreted as evidence of suffocation.

It was concluded that a definite cause of death could not be identified, neither in histologic examinations nor in toxicologic tests. It was discussed that the toxicologic tests covered a certain spectrum of substances only and would miss some rare and exceptional substances. Histology could not identify a definite cause of death either. Because of the combination of pulmonary emphysema and the fissures at the left corner of the mouth, which had been observed during the autopsy, death due to suffocation following violent obstruction of respiratory orifices could not be excluded. Likewise it could not be excluded that these findings were caused during the reanimation procedures.

MEDICAL CONDITION	START DATE	END DATE	CONTINUING
COMPLICATION OF PREGNANCY	Oct2009	Oct2009	No
HOSPITALIZATION	27Jan2010	18Feb2010	No

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>11 months.</p> <p>Further information will follow when available.</p> <p>Follow up information received on 8 September 2009:</p> <p>Concurrent medical conditions included malignant phenylketonuria.</p> <p>On 24 August 2009 the subject received 1st dose of Infanrix hexa and 1st dose of Prevenar.</p> <p>On 25 August 2009, 1 day after vaccination with Infanrix hexa and Prevenar, the subject experienced adverse drug reaction unspecified.</p> <p>The subject died on 25 August 2009, cause of death was not reported. It was unknown whether an autopsy was performed.</p> <p>Follow up information received on 5 November 2009:</p> <p>Lot numbers were provided.</p> <p>Follow up information received on 28 December 2009:</p> <p>Comment and conclusion from regulatory authority received.</p> <p>The parents were Armenian.</p> <p>Concurrent medical conditions included developmental motor delay (tested by AIMS: 4 months), phenylketonuria and dihydropteridin reductase deficiency.</p> <p>Concurrent medications included Co-careldopa (Carbidopa + levodopa), Calcium folinate (Leucovorine), Oxitriptan and BH4 (tetrahydrobiopterine).</p> <p>3 days before vaccination, the subject was seen by a physiotherapist who observed low-pressure mood, crying and tiredness.</p> <p>Vaccinations were started at age of 11 months (instead of 2 months age normally) due to miscommunication between physicians.</p> <p>The subject received Infanrix-hexa and Prevenar at 10:30 on 24 August 2009.</p> <p>The subject was not ill, no fever was observed. The baby experienced vomiting a few times that day and difficulties with defecation. She slept well and played normally the next morning.</p> <p>On 25 August 2009, the subject went to bed for a nap and her mother found her blue colored and not breathing at 13:00 in bed.</p> <p>On 25 August 2009, 1 day after vaccination with Infanrix hexa and Prevenar, the subject experienced asystolia.</p> <p>The subject died on 25 August 2009, cause of death was unknown.</p> <p>Pediatrician suggested (according forensic physician report) the possibility that the subtle balance on neurotransmitter level which is part of the underlying metabolic disorder has been disturbed.</p> <p>The unknown cause and the rare underlying disease make it difficult to assess the causality of vaccinations and death. The interval between vaccinations and death was longer than 24 hours and girl did not have fever, both make causality less likely. Most probably this is a coincidence and not an adverse reaction.</p> <p>No further information has been requested, the case has been closed.</p> <table border="0"> <tr> <td>MEDICAL CONDITION</td> <td>START DATE</td> <td>END DATE</td> <td>CONTINUING</td> </tr> <tr> <td>PHENYLKETONURIA</td> <td>Unknown</td> <td>Unknown</td> <td>Unknown</td> </tr> <tr> <td>DEVELOPMENTAL MOTOR DELAY</td> <td>Unknown</td> <td>Unknown</td> <td>Unknown</td> </tr> <tr> <td>TIREDNESS</td> <td>Unknown</td> <td>Unknown</td> <td>Unknown</td> </tr> <tr> <td>CRYING</td> <td>Unknown</td> <td>Unknown</td> <td>Unknown</td> </tr> </table>			MEDICAL CONDITION	START DATE	END DATE	CONTINUING	PHENYLKETONURIA	Unknown	Unknown	Unknown	DEVELOPMENTAL MOTOR DELAY	Unknown	Unknown	Unknown	TIREDNESS	Unknown	Unknown	Unknown	CRYING	Unknown	Unknown	Unknown

<p>On 6 October 2009, 12 hours at around 23:00 pm after vaccination with Infanrix hexa, RotaTeg and Synflorix, the subject experienced sudden unexpected death in infancy. The child was reanimated in hospital unsuccessfully.</p> <p>The subject died on 6 October 2009, cause of death was not reported.</p> <p>Follow up received on 19 October 2009 from the physician, head of the national vaccination board, not the treating physician: Results of the autopsy included cerebral swelling, congestion-hemorrhage; both might be leaded back to the reanimation for half an hour. The subject was found in abdominal position, therefore the physician supposed a sudden infant death syndrome. The virological investigation did not show anything relevant.</p> <p>Follow up received on 22 October 2009 including the QA statement: A complete review of the batch Synflorix has been performed. No</p>

deviation that could be linked to the complaint has been highlighted.				
Follow up received on 29 October 2009 from the regulatory authority: On 12 October 2009 the autopsy was performed, no macroscopic findings detectable at this time. The child was admitted to hospital under reanimation. Autopsy report was not available at the moment. Follow up was received from national vaccination board on 30 October 2009 and SIDS was confirmed.				
Follow up received on 27 April 2010 (protocol autopsy): Relevant test performed on 12 October 2009 included parechovirus test which was not detectable in the intestinal fluid, VZV, CMV, HHV6, HHV7, enterovirus, parvovirus, norovirus genotype I and II, rotavirus, astrovirus, norwalk like virus, influenza A and B and RSV test, all were negative.				
In the follow up received on 29 June 2010 it was mentioned that no further information was received. Therefore this case has been closed.

7. & 13. DESCRIBE EVENT(S) Respiratory arrest; Anaphylactic reaction; Pyrexia, A physician reported the occurrence of death possibly due to anaphylaxis in a 4 month old female who was vaccinated with DTPa-HBV-Polio/Hib vaccine (Infanrix Hexa) for prophylaxis. The pregnancy was normal, but after birth the subject had mild respiratory problems and was hospitalised for three days. There were no severe illnesses since birth. No hereditary diseases were known within the subject's family. The subject's brother, born on 01 January 1999, had epilepsy of unknown cause since the age of two years. The reporting physician also stated, that the grandparents of the subject had several deaths among their children, but no detailed information about this was available. On 16 April 2002 at 11:00 the subject received the first dose of DTPa-HBV-Polio/Hib vaccine, lot number 21H0027, intramuscularly right gluteal. There was no injection site reaction. 7. & 13. DESCRIBE EVENT(S)							
<p>of the same day the subject developed mild fever up to 38.7 degC, which was treated by a paracetamol suppository at 20:30. The subject was fed normally and brought to bed in lateral position. On 17 April 2002 at 8:30 the mother found the subject dead in bed, in prone position. An emergency physician was called but could only testify the subject's death. The cause of death was unknown, but a respiratory arrest was suspected. An autopsy was performed. According to verbal information from forensic medicine via the regulatory authority, the subject died from possible anaphylaxis.</p> <p>According to information received on 03 June 2002 the reporting physician considered that the possible respiratory arrest was not related to vaccination with Infanrix Hexa, while the forensic physician did not specify the causality of possible anaphylaxis.</p> <p>The autopsy was performed on 18 April 2002 and received on 03 March 2003 via the regulatory authority (PEI, case number 2680-2002). The possible anaphylaxis was not mentioned in the autopsy report. There was no indication for mechanic force or infection of the airways. The brain was very compact with severe congestion. The physician doing the autopsy suggested that this could possibly be due to hypoxia. The right side of the heart was dilated and the subject had arteria lusoria. There were several local bleedings in the region of the thymus, which was considered to be an indication for sudden infant death syndrome (SIDS). But the arterial vessels were dilated and thin with changes of the wall structure, which the physician could not assign to a concrete syndrome. For this reason he was not able to do a final evaluation. No signs were found for a relationship of the death to vaccination, but the physician also stated that it would probably need special examinations to clarify this. In the cover letter the physician stated that it was not possible to quantify the probability of a causal relationship between the death and the vaccination.</p> <p>An expert report received on 02 April 2003 stated the following: The autopsy findings and the general causes of cerebral oedema were reviewed with a Belgian opinion leader in Neuropathology. He concluded that the large thymus, with multiple bleedings under the capsule and on the surface of the cut were suggestive for SIDS. He actually identified that the signs for an oedema were very limited in this autopsy report. The presence of cerebral edema could only be suspected based on the decreased volume of the ventricles. The weight of the brain was within normal ranges. It would only be possible to conclude for the presence of oedema when additional histological analyses will be performed. If confirmed, the oedema present would most probably be of the "cytotoxic" type due to hypoxia, which may have many different causes at this age. Another expert report concluded that the reports did not produce any argument suggesting that the death was due to the vaccine and that the death was not a coincidental event.</p> <p>After an expert meeting in March 2003 virological PCR test results were received by the regulatory authority. The test showed negative values for Enterovirus, Adenovirus, Influenza A and Parainfluenza in the lung, for Enterovirus, Adenovirus, Influenza A, Parainfluenza and Parvovirus B19 in the heart and for Enterovirus, Adenovirus and Herpes simplex virus in cerebrospinal fluid. A low value for human Herpes virus 6 was found in cerebrospinal fluid, indicating an old but not acute infection.</p> <p>According to information received from the EMEA on 29 March 2004, the subject was a premature baby with very low birth weight (821 g) and possibly cardiac problems. The EMEA stated that it is not possible to conclude a causal relationship between the death and the immunisation with Infanrix Hexa.</p> <p>This case was mentioned without any case details in literature in 2009 within a general discussion on hexavalent vaccines and SIDS.</p> <p>Knuf M., Sutter U. Padiatr. Prax. 2009 74:2 (379-382)</p> <p>Autopsy on 18 April 2002: Result: no indication for mechanic force or infection of the airways brain very compact with severe congestion, possibly be due to hypoxia right side of the heart dilated arteria lusoria several local bleedings in the region of the thymus arterial vessels dilated and thin with changes of the wall structure</p> <p>Virological testing (PCR): Cerebrospinal fluid (CSF): negative for Enterovirus, Adenovirus and Herpes simplex virus, low value for human Herpes virus 6, indicating an old but not acute infection Lung: negative for Enterovirus, Adenovirus, Influenza A and Parainfluenza Heart: negative for Enterovirus, Adenovirus, Influenza A, Parainfluenza and Parvovirus B19</p> <table><tr><td>LABORATORY TEST NAME</td><td>TEST DATE</td><td>TEST RESULT</td><td>LOW NORMAL</td><td>HIGH NORMAL</td></tr></table>			LABORATORY TEST NAME	TEST DATE	TEST RESULT	LOW NORMAL	HIGH NORMAL

7. & 13. DESCRIBE EVENT(S)				
<p>On 13 February 2009 the subject received the third dose of Infanrix hexa (0.5 ml, intramuscular, right thigh) and the third dose of Prevenar (0.5 ml, intramuscular, left thigh), contralaterally.</p> <p>Approximately three days post vaccination with Infanrix hexa and Prevenar, on 16 February 2009, the subject dies from sudden infant death syndrome (SIDS). An autopsy was performed. The results of autopsy confirmed SIDS. At the time of reporting the autopsy report was not at hand.</p> <p>Follow-up information, including a preliminary autopsy protocol, was received on 27 April 2009 from the German regulatory authority (DE-Paul-Ehrlich-Institut).</p> <p>Autopsy was performed on an unspecified date in 2009. Superficial examination by eye showed no findings. Autopsy showed no external or internal malformations. Internal organs showed no pathologic findings on closer inspection. Thymus gland was very pronounced. Above the anterior cardiac wall the pericardial heart sac showed several punctual haemorrhages. The results of chemical - toxicological examinations were still pending. Considering anamnesis (subject found dead in bed) and assuming negative results of chemical - toxicological examinations the findings were basically consistent with diagnosis of sudden infant death syndrome (SIDS). Final assessment cannot be made until results of all pending examinations have been received. The subject's body was released for burial.</p> <p>Follow-up information, including a final autopsy protocol, was received on 06 April 2010 from the German regulatory authority (DE-Paul-Ehrlich-Institut).</p> <p>Histology of five samples of lung tissue showed mild chronic bronchitis and blood congestion but the lung tissue was otherwise normal. Histology of four samples of heart tissue showed blood congestion but was otherwise age-corresponding with normal heart muscle tissue. Histology of one sample each of brain tissue, liver tissue, renal tissue and spleen tissue were all normal and showed no relevant pathologic changes of the organs.</p> <p>No bacteriological examinations have been performed because all samples had been fixed in formaline.</p> <p>Overall histology showed no signs of inflammatory processes and no pathologic changes in tissue samples of the organs which could have caused the death of the subject. Therefore, assuming negative results of chemical and toxicological examinations, no reasons for a refusal of diagnosis of sudden infant death syndrome (SIDS) have been found.</p> <p>No further information will be available.</p> <p>CONCOMITANT DRUGS AND DATES OF ADMINISTRATION</p> <table><tr><td>Prevenar (Wyeth Labs) (Pneumococcal vac NonGSK)</td><td>16Jan2009 - 16Jan2009</td></tr></table>			Prevenar (Wyeth Labs) (Pneumococcal vac NonGSK)	16Jan2009 - 16Jan2009

7. & 13. DESCRIBE EVENT(S) Cardiac failure acute, Pulmonary oedema, Sudden death, Cardiopulmonary failure, Respiration abnormal, Tachypnoea, Myocarditis, Myocardial infarction, Haemostasis, This case was reported by a physician and described the occurrence of acute cardiac failure in a 5-month-old male subject who was vaccinated with combined diphtheria, tetanus-acellular pertussis, hepatitis B, inactivated poliomyelitis and Haemophilus influenzae type b vaccine (Infanrix hexa, GlaxoSmithKline) for prophylaxis. Co-suspect vaccination included pneumococcal vaccines (non-gsk) (Prevenar, Wyeth). On 30 April 2009 the subject received 3rd dose of Infanrix hexa and 3rd dose of Prevenar (unknown route and application site). According to subject's mother, the subject developed breathing not normal since the day of vaccination on 30 April 2009. At examination during doctor visit saturation and pulse were normal. At the time of reporting the outcome of the event was unspecified.						<input checked="" type="checkbox"/> PATIENT DIED AS OUTCOME OF EVENT <input checked="" type="checkbox"/> RESULTED IN OR PROLONGED INPATIENT HOSPITALISATION <input type="checkbox"/> INVOLVED PERSISTENCE OF SIGNIFICANT DISABILITY OR INCAPACITY <input checked="" type="checkbox"/> LIFE THREATENING <input type="checkbox"/> CONGENITAL ANOMALY <input type="checkbox"/> CLINICALLY SIGNIFICANT / REQUIRED INTERVENTION <input type="checkbox"/> OTHER

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>Follow-up information was received on 14 May 2009 by the physician. Previous vaccinations with Infanrix hexa and Prevenar were well tolerated. Subject's sibling also died suddenly at the age of 5 months without receiving prior vaccinations.</p> <p>On 30 April 2009 the subject received 3rd dose of Infanrix hexa (intramuscular, unknown application site left sided) and 3rd dose of Prevenar (intramuscular, right upper thigh).</p> <p>On 30 April 2009, less than one day after vaccination with Infanrix hexa and Prevenar, the subject died. Reanimation was ineffective.</p> <p>The physician considered death was possibly related to vaccination with Infanrix hexa and Prevenar.</p> <p>The subject died on 30 April 2009 from death NOS. An autopsy was performed on 7 May 2009.</p> <p>Follow-up information was received on 3 June 2009 by the physician. A targeted follow-up questionnaire was provided but not filled in. According to the physician it was not a sudden infant death. The subject died in hospital.</p> <p>Autopsy results were not available for the reporter.</p> <p>Follow-up information was received on 10 June 2009 by the physician via telephone call. Subject's brother showed same symptoms of abnormal breathing on 22 February 2007 after unspecified vaccination on 30 November 2006. The sibling died from cardiomegaly on 24 February 2007 in hospital. The physician did not see a relation to vaccination. Subject's parents consulted genetic advice, but a cause was not found.</p> <p>The subject was vaccinated at nine o'clock in the morning at a wide-awake general condition. Three hours after vaccination subject's mother had a doctor call and came for a doctor visit. There, the subject suffered from breathing not normal (tachypnea). Otherwise the subject was bright and awake.</p> <p>The subject was hospitalised for security due to anamnesis. At hospital subject's condition was normal except tachypnea.</p> <p>Approximately 40 minutes later tachypnea worsened significantly, the subject experienced cardiopulmonary failure and died of an unknown cause.</p> <p>The physician only considered vaccination as a trigger at an unknown genetic or familial predisposition.</p> <p>Follow-up information was received on 22 April 2010 from German regulatory authority Paul-Ehrlich-Institut (# DE-PEI-PEI2009009966).</p> <p>Following information was provided:</p> <p>Case narrative including clinical course, therapeutic measures, outcome and additional relevant information:</p> <p>A 5-month-old male patient was vaccinated with Prevenar, batch-no.: 36470 and with Infanrix hexa, batch-no.: A21CA482 for Prophylactic vaccination. Past medical history were not provided. 8 hours after vaccination the patient presented with Sudden infant death. An autopsy was performed. Further information is requested.</p> <p>Phone information of the pediatrician on 12.05. 2009:</p> <p>The baby was vaccinated in the morning in good status of health with Infanrix hexa and Prevenar.</p> <p>At about 12:00 am the parents presented again in the practice claiming that the baby was tachypnoic. The pediatrician found the baby in good status of health and sent them home.</p> <p>at 15:00 p.m the parent presented again in the practice and the baby was found a little bit tachypnoic but in good conditions of health.</p> <p>Due to the fact that the couple had lost another baby boy at the same age due to cardiopulmonary dysfunction (probably myocarditis) the physician admitted the baby to a hospital. At 15:30 p.m the baby was found in reduced status of health and tachypnoic.</p> <p>After 45 min and repeated reanimation attempts the baby died.</p> <p>Intensified diagnostics (post-mortem diagnostics in the hospital) as well as pathological diagnostics have been initiated.</p> <p>Additional information was received regarding the events, patient's demographics, dose details, medical history and outcome.</p> <p>Information regarding Prevenar (pneumococcal 7-valent conjugate vaccine (diphtheria crml97 protein) syringe pre-filled) was received from a healthcare professional regarding a 5-month-old male patient who experienced tachypnoea and who died of sudden death. The patient received the third dose on 30-Apr-2009.</p> <p>MEDICAL HISTORY:</p> <p>Past vaccinations included the first two doses of Prevenar (pneumococcal 7-valent conjugate vaccine (diphtheria crml97 protein) syringe pre-filled) and Infanrix hexa (diphtheria vaccine/tetanus vaccine/acellular pertussis vaccine/polio virus inactivated/haemophilus influenzae b/hepatitis b vaccine). One of the patient's siblings died of fulminant cardiomyopathy at the same age. The sibling has received the last</p>

<p>vaccination 2.5 months prior to date of death.</p> <p>PRODUCT DETAILS:</p> <p>Indication for Prevenar was immunisation. Product was administered in right thigh at 9.20 am on 30-Apr-2009. Dose regimen was 1 dose 1 time per day (intramuscular).</p> <p>Additional suspect medication included Infanrix hexa (diphtheria vaccine/tetanus vaccine/acellular pertussis vaccine/polio virus inactivated/haemophilus influenzae b/hepatitis b vaccine) which was administered in left thigh on the same time.</p> <p>CONCOMITANT THERAPY:</p> <p>Concomitant medications were not reported.</p> <p>EVENT DETAILS:</p> <p>After vaccination the parents went twice to the doctor with the patient on the same morning. The patient experienced mild tachypnoea (tachypnoea). The patient was clinically without severe findings. The second visit to the doctor was approximately three hours after the vaccination and during the visit the doctor decided to hospitalize the patient due to the death of the patient's sibling. Therefore the patient's parents took the patient to hospital for monitoring. The way to hospital was without any complications but on arrival at hospital the patient's condition impaired and the patient received permanent drop infusion for example. 40 minutes after the arrival at hospital the patient's condition got really worse so that reanimation was performed but without success. The patient died of sudden death on 30-Apr-2009. An autopsy was performed but at the time of report the result was unknown.</p> <p>The reporting physician's assessment of relatedness between the adverse events and Prevenar and Infanrix hexa was possible related.</p> <p>The cause of death was reported as sudden death.</p> <p>No additional information was available at the time of this report.</p> <p>Follow-up information was received on 28 July 2009 by the prosecutors' office:</p> <p>The cause of death and manner of death were unknown at the date of the autopsy result. Further results of histological and toxicological examinations are requested.</p> <p>Follow-up information was received from prosecution on 20 April 2010:</p> <p>The results of histological and toxicological examinations were not yet available at the date of this report.</p> <p>Follow-up information was received on 9 August 2010 from regulatory authority.</p> <p>Results of histological and toxicological examinations included significant findings like heart cell necrosis, lymphocytic myocarditis, and haemorrhagic pulmonary edema as well as acute blood congestion in spleen, liver, adrenal glands and kidneys. Indications of active ingredients were found (probable substances which were administered during emergency treatment at intensive care unit. Cause of death was cardiac failure left side and pulmonary edema cardiac cause.</p> <p>No further information will be available.</p>

<p>7. & 13. DESCRIBE EVENT(S)</p> <p>(0.5 ml, unknown, left thigh), contralaterally.</p> <p>Less than one week post vaccination with Synflorix and Infanrix hexa, on an unknown date in August 2009, the subject experienced fever. Fever was resolved after one day.</p> <p>Approximately seven days post vaccination with Synflorix and Infanrix hexa, on 24 August 2009 at around 18:00, the subject died from possible sudden infant death syndrome (SIDS).</p> <p>An autopsy has been applied for. At the time of reporting, on 25 August 2009, autopsy was performed.</p> <p>Follow-up information including autopsy report was received on 14 December 2009 from the German regulatory authority (DE-Paul-Ehrlich-Institut # DE-PEI-PEI2009018995).</p> <p>Medical history included normal course of pregnancy and regular visits of a paediatrician for child health checks.</p> <p>On 17 August 2009 the subject was vaccinated with Synflorix and Infanrix hexa.</p> <p>On the next day, on 18 August 2009, the subject experienced mild fever.</p> <p>The subject died on 24 August 2009 at around 18:30 at home. The nearly 3-month-old male subject was found dead on 24 August 2009 at around 19:00 by the subject's mother.</p> <p>An autopsy was performed on 27 August 2009 at 08:30. The autopsy report was dated 17 November 2009.</p> <p>Macroscopically autopsy showed normal general and nutritional condition, no signs of malformations, bloody foam in respiratory tract, bloody wet lung, no signs of punctual hemorrhage at serous membranes, and no signs of mechanical external force. Microbiological examinations showed no bacteria in cerebrospinal fluid (CSF) and in blood from heart, Staphylococcus aureus and Escherichia coli in pulmonary swab, as well as Staphylococcus aureus, Moraxella catarrhalis and Escherichia coli in pharyngeal swab. Histology showed mucous-hemorrhagic inflammation of respiratory tract with mixed cell infiltration of mucous membrane of respiratory tract, in parts acute bloating of lung tissues next to areas with underventilation, activation of bronchus associated lymphatic tissue, acute blood congestion in lungs, focal inflammatory pulmonary infiltrations, in parts with multinuclear giant cells; a singular round-cell infiltration in heart muscle, so called tubular heart muscle change; acute blood congestion in the liver.</p> <p>Autopsy, as well as subsequent microbiological and histological examinations, showed severe infection of respiratory tract and to a lesser extent of lungs above all with bacteria of the species Staphylococcus aureus. Furthermore, histology showed a single inflammatory focus in the heart muscle. With reservation of outstanding results of chemical-toxicological examinations the findings were consistent with death within the scope of inflammation of respiratory tract with involvement of the lungs and accompanying myocarditis. No signs of external mechanical force have been found, but killing with low evidence, e. g. soft covering of mouth and nose, cannot be excluded. The subject's body was released for funeral.</p> <p>Follow-up information was received on 15 January 2009 from the German regulatory authority (DE-Paul-Ehrlich-Institut).</p> <p>The case has been reassessed. Initially suspected sudden infant death syndrome (SIDS) was excluded by autopsy and therefore has been deleted as adverse event.</p> <p>No further information will be available.</p> <table border="0"> <tr> <td>LABORATORY TEST NAME</td> <td>TEST DATE</td> <td>TEST RESULT</td> <td>LOW NORMAL</td> <td>HIGH NORMAL</td> </tr> <tr> <td>Head circumference</td> <td>24Aug2009</td> <td>41cm</td> <td></td> <td></td> </tr> </table>			LABORATORY TEST NAME	TEST DATE	TEST RESULT	LOW NORMAL	HIGH NORMAL	Head circumference	24Aug2009	41cm
